M.S.—Candidates for this degree must have been engaged in practice for at least two years subsequent to becoming M.B., B.S. Durham. They are submitted to an examination which covers the whole range of surgical knowledge.

D.Ch.—The University grants also the Degree of Doctor of Surgery. Candidates for this degree must be registered medical practitioners, not less than 24 years of age. They must devote three years, subsequently to obtaining a registrable qualification, to the study of surgery and ancillary subjects; one at least of the three years must be spent in the university. The candidate must submit to the professor of surgery the course of study he proposes to follow, and this course must be approved by the Board of the Faculty of Medicine.

One year shall be devoted mainly to work in the departments of anatomy, physiology, pathology, and bacteriology, and the candidate must submit evidence of having so worked. Not less than six months of another year must be spent as a resident surgeon in a recognized teaching hospital, and the rest of the year in the study of surgery in a recognized medical centre. Not less than six months of one of the three years must be spent in surgical study abroad.

## FEES.

The following fees are payable: Matriculation or its equivalent, £2; First, Second, and Third M.B., B.S. Examinations, each £5; Final M.B., B.S. £15; M.D. and M.S. £5 for each examination; The fee for the degree of D.Ch. is £20, and the fee for the degree £10.

Further information may be obtained from Professor Howden, Registrar, University of Durham College of Medicine, Newcastle-on-Tyne.

## UNIVERSITY OF LEEDS.

The degrees granted in the Medical Faculty of this university are Bachelor of Medicine, Bachelor of Surgery (M.B. and Ch.B.), and Bachelor of Dental Surgery (B.Ch.D.), Doctor of Medicine (M.D.), Master of Surgery (Ch.M.), and Master of Dental Surgery (M.Ch.D.). It also gives diplomas in public health, in psychology, and in dental surgery. Candidates for the M.B. must have attended courses of instruction approved by the university for not less than five

advises immediate operation in nearly all cases, the operation only being postponed if the child is not viable and a viable child is greatly desired, the patient being able to be kept under the closest observation. Waiting for spurious labour to occur and the child and placenta to die before operation is deprecated on the ground that, though the placenta can be easily separated, the sac is still firmly adherent and its separation will cause much bleeding. With regard to the placenta, the author only advocates removal when the sac with placenta can be tied off at both ends, which will only be possible in a tubal or tubo-ovarian pregnancy; in other cases packing of the sac with iodoform gauze is advised, and the wound either closed or the sac marsupialized. By the former method the placenta is partially absorbed and partially becomes calcareous; it usually gives rise to no untoward symptoms, but if symptoms do develop laparotomy can be done. If marsupialization is done the placenta should not be pulled on until separation is complete, as fatal bleeding may be encountered if it is still partly adherent. Sloughing and necrosis may occur by such methods of treatment, but they are infinitely preferable to bleeding, which is often fatal.

#### 156. Cure of Eclampsia Coma by Unilateral Renal Decapsulation.

A. NIEDERMEYER (*Deut. med. Woch.*, June 8th, 1923, p. 756) has recently observed two cases in which unilateral renal decapsulation was performed at a time when patients suffering from eclamptic coma were practically moribund. In his second case the effect of the operation was dramatic; as soon as the operation had been performed there was an improvement in the respiration and pulse, and though the scanty urine passed before the operation had turned solid on boiling, there was only a trace of albumin in the urine on the day following the operation. The author suggests that the beneficial effect of renal decapsulation in such cases depends on the mechanical relief of pressure, and he uses the term "glaucoma of the kidneys" to explain the mechanism of decapsulation. It would seem that when intrarenal pressure has reached a certain level the secretory functions of the renal parenchyma are completely inhibited. It is sufficient to perform decapsulation only on one side, and considering how critical the patient's condition is in the cases in which this operation is undertaken, it would be dangerous as well as superfluous to strip the fibrous capsules off both kidneys. It appears that when the pressure of one kidney is relieved, the functions of the other will gradually return without its capsule being opened.

#### 157. Oligohydramnios.

M. W. SCHELTEMA (*Nederl. Tijdschr. v. Geneesk.*, July 28th, 1923, p. 353), who emphasizes the rarity of oligohydramnios, or the occurrence of only a few cubic centimetres of amniotic fluid, records a case in a primipara, aged 26, in which there was no fluid but merely a clear colourless syrupy mass which could best be called amniotic jelly, and was present only between the membranes and the skull. The child was covered with a remarkably thick layer of vernix caseosa. The membranes themselves were so thick that it was impossible to rupture them with the finger and they had to be snipped with scissors. Scheltema has been unable to find any description of such remarkably thick membranes in the literature. The child was a female weighing 3,650 grams, and did not present any malformations.

### Pathology.

#### 158. The Anti-anaphylactic Action of Lipoids.

ACCORDING TO C. DUPREZ (*C. R. Soc. de Biologie*, July 7th, 1923, p. 420), if a guinea-pig, previously injected with horse serum, be injected intravenously with a saline emulsion of the lipoids obtained from an alcoholic extract of calf's heart, its sensitivity is so diminished that no shock is apparent on the administration of the dechaining dose. The effect of the lipoids is to produce a state of anti-anaphylaxis. On what does this action depend? To elucidate this he mixed 5 c.cm. of fresh guinea-pig serum with 0.5 c.cm. of an emulsion of lipoids, incubated for one hour at 37° C., centrifuged, and removed the supernatant layer of lipoids. To the remaining liquid he added 1 c.cm. of a 0.5 per cent. suspension of agar, incubated the mixture for one hour, and centrifuged it the following day. The supernatant fluid was injected into a guinea-pig, which died within a few minutes. From this, and from another similar experiment, he concludes that the anti-anaphylactic action of lipoids is not of the nature of an adsorption phenomenon. Working with guinea-pigs rendered allergic by intraperitoneal injection of dead tubercle bacilli, the same author found it was possible to produce

iodide. After preliminary treatment with tubercle bacilli two animals were obtained which reacted to the intradermal injection of tuberculin by the production of a papule 3 cm. in diameter. A daily injection of 1 c.cm. of a 5 per cent. solution of potassium iodide was then given subcutaneously to each animal for ten days. At the end of this time the reaction to tuberculin was limited to a papule of only 1.5 cm. in diameter. Another series of potassium iodide injections was given for ten days, after which the skin reaction to tuberculin had disappeared completely. A week later, however, the allergic reaction was present in the same intensity as before.

#### 159. The Leucocytes in Health and in Disease.

K. D. FAIRLEY (*Med. Journ. of Australia*, June 16th, 1923, p. 655) gives a good general review of our present knowledge of the physiological and pathological activities of the white blood corpuscles. In the light of recent work which has been conducted in various countries throughout the world it would appear that the usually accepted blood formula must be modified. Instead of the polymorphonuclear cells being present in three times the number of the mononuclears, it is probable that in the normal blood they show not more than a slight excess. The average for a large number of estimations gives a relative proportion of 54.6 per cent. for the polymorphs and 45.3 per cent. for the mononuclears. But it is important to remember that in the individual case such wide variations may be found that little significance can be attached to the average. Of far greater value in the interpretation of the single blood count is a knowledge of the normal variations above and below the mean. These variations, the author points out, are greater than is usually supposed. He regards the normal physiological variation of the total leucocyte count as lying between 4,500 and 15,000 per c.mm.; the relative proportion of the polymorphonuclear cells is probably between 30 and 80 per cent. Failure in the past to realize the possibility of such a low polymorph percentage as 30 being compatible with normality has been responsible for the erroneous interpretation of high lymphocyte counts in healthy persons.

#### 160. Tracheitis due to Pfeiffer's Bacillus.

G. ROSENTHAL (*Paris Méd.*, July 28th, 1923, p. 89) states that in his inaugural thesis of 1900 he showed that there was no parallelism between influenzal syndromes and infections caused by Pfeiffer's bacillus, the latter being as frequent an inhabitant of the respiratory tract as *B. coli* is of the intestine. This view was subsequently confirmed by Professor Bezançon and De Jong as well as by a large number of bacteriologists. He has recently seen a case of mild haemorrhagic tracheitis of ten days' duration with little rise of temperature and no prostration in a patient aged 50, whose principal complaint was the expectoration of thick blood-stained sputum in the morning. The mild course of the disease, the absence of emaciation, and the normal character of the respiratory murmur excluded pulmonary tuberculosis, and there was nothing to justify the diagnosis of influenza. Bacteriological examination showed that the sputum was swarming with Pfeiffer's bacilli. Rosenthal refers to the article by Lisbonne and Leenhart on Pfeiffer's bacillus meningitis (*see EPITOME*, March 10th, No. 210), which, like the tracheo-pulmonary localizations, cannot be regarded as a manifestation of influenza.

#### 161. The Value of Egg Yolk in Rickets.

IN view of the high content of fat-soluble vitamin in yolk of egg, and the close association in nature of this vitamin with the antirachitic factor, as best exemplified in cod-liver oil, it appeared worth while to A. F. HESS (*Journ. Amer. Med. Assoc.*, July 7th, 1923, p. 15) to test the potency of the yolk in relation to its prophylactic and curative value in rickets. Rats were fed on a low phosphorus diet, as a basic rickets-producing dietary, and to this diet 0.5, 0.3, and 0.25 gram of egg yolk was added daily. Experiments showed that egg yolk is able not only to protect young rats from rickets, but also to cure them of rickets. On the other hand they showed that white of egg is not merely devoid of antirachitic properties but seems to enhance the rickets-producing quality of a dietary. The yolk of one egg was added to the regular formulae of each of twelve infants, in the attempt to forestall the occurrence of rickets and the seasonal ebb of the blood phosphate. In most instances this addition was made in December, when the tendency to rickets becomes acute. By this simple supplement to the diet all the infants were protected from rickets, as judged by clinical, x-ray, and chemical criteria. The percentage of inorganic phosphate in the blood, instead of falling to 3.6 mg., the ebb observed last March, was maintained at 4 mg. or more, a level encountered during the summer months. The calcium content of the serum also was unusually high. It seems evident, from these data, that yolk of egg possesses considerable protective value in rickets.

a diploma in bacteriology; and a degree and diploma in dental surgery. Candidates for degrees must pass the special Matriculation Examination prescribed by the Faculty of Medicine (or some equivalent examination accepted in lieu thereof; see the prospectus of the Joint Matriculation Board), and study at the university itself for at least two years of the six years' curriculum, one such year being subsequent to the passing of the first M.B. Examination. The Matriculation Examination comprises (1) Latin, (2) mathematics, (3) the English language, its literature and history; (4) two subjects at choice, one of which must be a language approved by the Joint Board, the other being elementary mechanics or physics, chemistry, geography, natural history, or botany. It is held in July and September.

#### PROFESSIONAL EXAMINATIONS.

M.B., Ch.B.—There are four examinations for this degree. They must be passed in proper order, and before admission to them the candidate must be duly certified as having attended in the subjects involved. At all examinations the subjects, or groups of subjects, prescribed can be taken separately or together, as the candidate pleases. The first M.B. is divided into Part I, chemistry and physics; Part 2, biology; (a) botany, (b) zoology. The parts may be taken separately or together. At the second M.B. the candidate is examined in anatomy and physiology; at the third in pathology and pharmacology (including materia medica and practical pharmacology). The Final Examination is divided into two parts, which may be taken separately, and includes medicine, systematic and clinical, mental diseases, and diseases of children, surgery (systematic, clinical, and practical), obstetrics and gynaecology, preventive medicine, forensic medicine and toxicology.

M.D.—A candidate for this degree must be a bachelor of medicine of at least one year's standing. He has a choice between presenting an original dissertation or undergoing a written (as well as practical and clinical) examination in medicine, and a written and practical examination in pathology, and one other subject selected by himself. Ch.A.—A candidate must have held, since becoming Ch.B., and for not less than twelve months, a post in a public institution affording opportunity for the study of the branch of surgery in which examination is desired. The examination in Branch I comprises the general field of surgery; Branch II obstetrics and gynaecology; Branch III ophthalmology; Branch IV ology, laryngology, and rhinology.

#### FEES.

The following fees are payable: Matriculation, £3; on re-admission, £1 10s. Each M.B. examination, £3 8s; on readmission, after failure, £3 3s. M.D., including the conferring of the degree, £15 15s. Ch.A., £6 6s. for the examination and £9 9s. for conferment of degree. Application for further information should be addressed to the Dean of the Medical Faculty.

#### UNIVERSITY OF SHEFFIELD.

The degrees of this university (M.B., Ch.B., M.D. and Ch.A., B.D.S. and M.D.S.), the diploma in public health, and the diploma of licentiate in dental surgery, are open to candidates listed in the university or have passed such other examination as may be recognized for this purpose, and have passed the further examination in chemistry and physics.

#### PROFESSIONAL EXAMINATIONS.

A candidate for the degrees of M.B., Ch.B. must produce certificates that he will have attained the age of 22 years by the day of graduation; that he has pursued the courses of study required by the university regulations during not less than five years subsequent to the date of his matriculation or exemption from matriculation, and the passing of the further examination in chemistry and physics, three of such years at least having been passed in the university, one at least being subsequent to the passing of the first examination. The following examinations must be passed in due order. First Examination.—The subjects are chemistry, physics, and biology. The intermediate examination in science—chemistry, physics, and zoology—will, on payment of the

#### UNIVERSITY OF WALES.

The Charter and statutes of the University of Wales provide inter alia for a Faculty of Medicine and for the granting of the following degrees: Bachelor in Medicine (M.B.), Bachelor in Surgery (B.Ch.), Master in Surgery (M.Ch.), and Doctor in Medicine (M.D.).

A candidate for the M.B., B.Ch. is required to pursue a course of study of not less than six academic years subsequent to matriculation in the university, and of these years at least three must have been passed as a student in one of the constituent colleges of the university. These are the University College of Wales, Aberystwyth; University College of Wales, Bangor; University College of South Wales and Monmouthshire, Cardiff; and University College, Swansea. He must also hold an Arts or Science degree of the University of Wales, or of some other university approved for this purpose. Certain of the courses of study pursued for a B.Sc. or B.A. degree may be counted as part of the courses required for the degrees in the Medical Faculty. The courses for the M.B., B.Ch. are divided into two sections, of which the first includes the preliminary subjects—physics, chemistry, botany, zoology; and the auxiliary subjects—organic chemistry, human anatomy, and physiology. Study of the preliminary subjects and of organic chemistry must extend over at least one academic year; study of physiology and anatomy must extend over at least two academic years, and cannot be commenced until all the preliminary courses have been completed; hence the first section of the course must occupy not less than three years. The second section includes courses in pathology, bacteriology, pharmacology, medicine, surgery, and obstetrics and gynaecology, and cannot be commenced, except in the case of pharmacy, until the examinations relating to the preliminary and auxiliary courses have been passed. Examinations in the earlier subjects are held at the end of each academic year, and in the subjects of the second section each July.

Other information concerning this university will be found in the section devoted to Provincial Medical Schools.

M.D.—Candidates for the degree of Master of Surgery must have passed the examination for the degrees of M.B., Ch.B., at least one year previously, and must, since taking the degrees of M.B., Ch.B., have held for not less than six months a surgical appointment in a public hospital or other public institution affording full opportunity for the study of practical surgery. The subjects of examination are systematic, clinical, and operative surgery, surgical anatomy, surgical pathology, and bacteriology.

M.D.—Candidates for the degree of Doctor of Medicine must have passed the examination for the degrees of M.B., Ch.B., at least one year previously, must present a thesis embodying observations in some subject approved by the Professor of Medicine, and must pass an examination in the principles and practice of medicine.

Ch.A.—Candidates for the degree of Master of Surgery must have passed the examination for the degrees of M.B., Ch.B., at least one year previously, must present a thesis embodying observations in some subject approved by the Professor of Medicine, and must pass an examination in the principles and practice of medicine.

Third Examination.—The subjects are pathology and pharmacology, anatomy and physiology. Candidates must have completed the fourth winter of medical study and the requisite courses in these subjects, including post-mortem clerkship for three months.

Final Examination.—The subjects are medicine (including forensic medicine, public health, mental diseases, and diseases of children), surgery, and obstetrics (including gynaecology). Candidates must have completed the fifth year of study.

declarations to the contrary, steadily gaining ground over tuberculosis.

The last example I need cite is the prevention of a high infant mortality. At the end of the nineteenth century there died every year in England and Wales 150 infants per 1,000 born. In many industrial districts the figure was 300. In 1922 it had fallen for the whole country to 77. What has happened here? No doubt many factors have contributed, but the most potent have been more enlightened motherhood and infant nurture.

Now here we have four examples of the effect of preventive medicine applied to the community through the operations of the State or the municipality. They have effected a postponement of death and an enormous betterment of man's physical condition and capacity. But it was Medicine, medical science and medical art, which first determined the causes or conditions of these diseases, and then conceived the means of their prevention. Many and complex have been the factors at work, but in the four examples quoted (a) improved sanitary environment, (b) vaccine, (c) personal and social hygiene, and (d) enlightened motherhood, emerge as dominant.

### SOME UNDEFEATED ENEMIES.

We must now take a further step in the argument, and ask ourselves if preventive medicine can be applied to other morbid conditions, which, though not national or racial scourges, do, in fact, prove themselves to be the most formidable enemies we have to face. What are they? There are two bodies of data immediately at hand. There were 486,780 deaths in 1922. The chief cause was respiratory disease (non-tuberculous), responsible for 18 per cent.; next came diseases of the heart and circulation, 16 per cent.; then nervous diseases and cancer, 10 per cent. each; then tuberculosis 9 per cent. So that 63 per cent. of the total number of deaths was due to five great groups of disease. What has preventive medicine to say to these? There is another body of data which illumines the situation—namely, the causes which take upwards of seven million patients to their insurance doctors every year. A survey was made in 1921 of 36,000 cases in 226 practices in 116 towns, and it was found that 22 per cent. went to the doctor with respiratory disease (mainly bronchitis), 13 per cent. with digestive disease, and 45 per cent. with influenza, anaemia, skin disease, minor injuries and accidents, septic conditions, lumbago and rheumatism, and debility. Thus we know approximately 80 per cent. of the early morbid conditions met with in average insurance practice. What has preventive medicine to say to this group? Clearly, it should have more to do with them than with the ultimate causes of death. But taking both groups together, with the exception of cancer, they constitute the chief current burden of preventable mortality, sickness, incapacity, and "lost time" from the industrial point of view. This is now the unconquered territory. Preventive medicine has proved itself efficacious in the realm of infection; it must turn its attention to this larger issue, for it possesses the potentiality to deal with it also.

The problem before us at the moment is not the action the State should take in regard to these diseases, nor even the work of the medical practitioner, essential as they both are. It is the narrower engagement, How can the medical curriculum be permeated with the spirit and methods of prevention? I think the answer is twofold. First, by the teachers of medicine conducting the studies of their pupils in the direction of prevention (a) by a special course in hygiene and preventive medicine, and (b) by addressing themselves to the preventive aspects of clinical work; secondly, by the student bending himself to preventive study.

A COURSE IN PHYSIOLOGICAL HYGIENE AND PREVENTIVE -  
MEDICINE.

The celebrated medical school in the University of Salerno possessed, as early as the twelfth century, a department of instruction in the basic subject of the Conservation of Health, and its sanitary precepts and principles have been handed down to us in the records and poems of the *Schola Salernitana*. Every British Medical School has

had something of this kind. But we do not make enough of it. It calls rather urgently for reform and amplification, partly as a definite and prescribed course in hygiene, and partly by the introduction into physiology and the clinical subjects of the preventive view. There should be a living and comprehensive short course in hygiene—not "drain," and nuisances, but the vital principles and means of health and the widest understanding of the physical effect of his environment and habits on man. We make the student, by special courses, familiar with anatomy and physiology that he may have the normal in his mind, and on that we build up his conception of disease. Why not start all his clinical work on a similar basis by providing a course in *Hygiene* of the normal body in action, and the factors which affect it? Again, *Medicine* proper should always and invariably include instruction in the prevention of disease of the respiratory, alimentary, circulatory, and nervous systems. There is a cause for all these morbid conditions, and Pasteur urged that the cause should be continuously sought and explored. *Surgery* likewise includes, and in some ways embodies in its most graphic form, the means of prevention; the removal of enlarged tonsils and adenoids, the correction of deformities, antiseptics, much abdominal and thoracic surgery, gynaecology, dentistry, industrial surgery, surgical reconstruction and re-education are examples which leap to the eye, but there are many others. *Obstetrics* should place in the foreground (and not in the background) the whole question of pre-natal supervision, puerperal fever, the prevention of congenital syphilis, ophthalmia, and the care of the infant, as well as the improved management of labour. What is really the scientific use and educational value of sending an inexperienced student to attend the confinement of a woman, whom he has never seen before, and of whose physical history he knows nothing? Is it only that he may count the case in the necessary twenty he must attend?

Even more important than the spirit of prevention pervading all instruction is the whole attitude of the student to his clinical work. I want him to ask himself, every time: "*Why is this patient here?* What is the physical or social complex that has made his body depart from the normal? To what stresses and exhaustion has he been subjected? How did he *get* this thing that troubles him and me?" Certainly, it is not chance, caprice, or fate. It is our business and our science to worry out the causes, and discover the way to escape or remove them. If every student became thus an investigator and discoverer, the science and art of medicine would be saved from perfunctory workmanship, and from explanations which are no explanations, what Cullen used to call "the most absolute languor" leading to "exclusive attachment to one system." We ought to welcome light from any source, orthodox or heterodox, frequently question all our methods, and even receive cheerfully "the noise and bustling of Paracelsus." As Henry Ford of motor-car fame says, "Everything can always be done better than it is being done."

## THE PHILOSOPHY OF PREVENTION.

The preventive attitude of the student cannot merely be left to opportunity. It must be provided for. In the first place, he should get a clear and fair "scratch line." He must know the physiological standard of health and capacity from which he starts. The preventive purpose of the course in anatomy and physiology is to teach him the range and capability of the human body, what Nature can and cannot do. "Our natures," said Hippocrates, "are the physicians of our diseases;" and, following him, in the Introduction of his *Medical Observations*, Thomas Sydenham, our grand exemplar in the seventeenth century, repeated the axiom: "Nature by herself determines diseases, and is of herself sufficient in all things against all of them." The study of biology, chemistry, and physics and the intermediate subjects, is to give an apprehension and standard of Nature which we may bring to the bedside. Without it we are lost, and prevention has no meaning. The natural history of disease is the crucial requirement. "When it is thoroughly grasped," says Sir Thomas Lewis, "that infection has more to do with heart failure than has strain or a mechanical defect in the heart itself

The conditions for admission of graduating students of medicine are the same as those in the Faculties of Arts or Science (for degrees in pure science).  
As from January 1st, 1923, prospective medical students are also required to pass a pre-registration examination in chemistry and physics.

#### PROFESSIONAL EDUCATION.

The regulations comply in all respects with the requirements and recommendations of the General Medical Council, and in addition necessitate definite study for stated periods of diseases of children, of the larynx, ear and nose, of skin, of ophthalmology, and of mental diseases. In respect of the various courses certificates must be obtained showing that the student has not only attended regularly, but has duly performed the work of the class. Out of the necessary five years of medical study, not less than two must be spent at the university whose degrees the student hopes to obtain, and the balance at any place officially recognized for such purpose. In each academic year there are two sessions—one lasting from the beginning of October to the middle of March, and the other from the beginning of May to the middle of July.

#### PROFESSIONAL EXAMINATIONS.

The distinctive feature of the Scottish curriculum is that, though normally there are only four examinations, each of these may be, and habitually is, split up by the student into sections. Hence, a student may complete some stage of his career during the course of nearly every session. Thus, by the end of the first winter session the student may pass in zoology and chemistry. At the end of the first summer session he can finish with botany and physics, and with anatomy and physiology at the end of the second. Pathology and materia medica he will pass at the end of the third year, and so on, until the final examination in midwifery, surgery, and medicine, and the corresponding clinical subjects at the end of the fifth year of study. At each examination the candidate may pass "with distinction," and a record is kept of the merit displayed, so that, when the time comes for the candidate to be declared as graduated with first or well throughout can be declared as graduated with first or second class honours. A further point in the system is that the student's own teachers commonly take some part in his examination.

Of the four examinations, the first deals with physics, botany, zoology, and chemistry; the second with anatomy and physiology; the third with materia medica and pathology; the fourth with medicine and surgery (clinical and systematic), midwifery, forensic medicine and public health, and clinical gynaecology. The first three examinations are held three times a year; the final twice a year. Exemption from the first professional examination can be obtained by candidates who have passed an arts or sciences degree examination in its subjects at any recognized university. When a candidate presents himself for an examination in several of its parts, but is not successful in all of them, he is credited at the next examination with those subjects in which he has already been approved.

#### THE HIGHER DEGREES.

It is open to those who are already M.B., Ch.B., to proceed either to the M.D. or the Ch.M. A candidate for the former must have been engaged for not less than one year in work in the medical wards of a hospital, or in scientific research in a recognized laboratory, or in the Naval or Military Medical Services, or have been at least two years in general practice, and he must be 24 years of age. He has to write a thesis on any subject not exclusively surgical, and is examined in clinical medicine and in some one or other of its special departments. The regulations for candidates for the Ch.M. are of a corresponding character, a period of surgical work in a hospital or elsewhere being substituted for medical work, and the thesis being on surgical rather than a medical subject. He is examined in surgical anatomy, clinical surgery, operative surgery, and in some of the special departments of surgery.

The College also issues a diploma (L.D.S.) in dentistry.

#### SOCIETY OF APOTHECARIES OF LONDON.

Thus body confers a registrable diploma in medicine, surgery, and midwifery, now known as the L.M.S.S.A. (Licentiate in Medicine and Surgery of the Society of Apothecaries), on those successful at the following examinations:

**Primary Examination.**—This is divided into two parts, of which Part I includes elementary biology, chemistry, chemical physics, practical chemistry, pharmacy. Part II includes anatomy, physiology, and histology, and cannot be passed before the completion of twelve months' practical anatomy with demonstrations. Candidates will be excused any or all of the subjects of the primary examination on producing evidence that they have passed equivalent examinations before an examining body recognized by the Society. Candidates referred in anatomy will be required to produce evidence of further work in the dissecting room before being admitted to re-examination.

**Final Examination.**—This is divided into three parts. Part I includes clinical surgery, the principles and practice of clinical medicine; (a) The principles and practice of medicine (including therapeutics, pharmacology, and prescriptions), pathology, and morbid histology; (b) forensic medicine, hygiene, theory and practice of vaccination, and mental diseases. Part III includes midwifery, gynaecology, and diseases of newborn children, obstetric instruments and appliances.

The fee for the primary examination is £5 5s; for the final, £15 15s. The regulations and synopses relating to the several examinations, and other information, may be obtained from the Secretary, Court of Examiners, Apothecaries' Hall, Blackfriars, E.C.4.

## The Scottish Universities.

There are in Scotland four universities, each possessing a faculty of medicine, and having the right to confer degrees which admit the holder to the *Medical Register*. In essential points the regulations in their medical faculties for undergraduates are much alike, so that a general account can be given of all of them together.

The universities are those of Edinburgh, Glasgow, Aberdeen, and St. Andrews. The provision each of the cities in which these universities are situated makes for the education of medical students will be found in the section on Medical Schools in Scotland; here it need merely be said that degrees in medicine from Scotland as a whole have always enjoyed a high repute.

The degrees granted in medicine and surgery to candidates of either sex are four in number—Bachelor of Medicine (M.B.), Bachelor of Surgery (Ch.B.), Doctor of Medicine (M.D.), Master of Surgery (Ch.M.). The two former are not obtainable one apart from the other. Besides these degrees a diploma in tropical medicine and hygiene is obtainable from the University of Edinburgh, as also diplomas in psychiatry and public health. As for public health, registrable degrees in this subject are granted by the Universities of Edinburgh and Glasgow, while diplomas in public health may be obtained from the Universities of St. Andrews and Aberdeen.

the student from this aspect and afterwards from the curative and reparative side. It will be obvious that touch should be kept with cases of puerperal fever and with the female venereal disease department, if the preventive aspect of infections is to be fully illustrated.

Having completed his training in clinical medicine and surgery, in which the diagnosis of disease and injury and their treatment and repair in the individual patient have been studied, the student comes to the reproductive function, not essential to the life of the individual but essential to the life of the race, and the opportunity must now be taken to make him think in terms of the community as well as of the individual and realize that he will have a place in a team working to improve the national health and physique. Once he can visualize the work of the maternity department with its follow-up sides, the gynaecological department, and the infant clinics, his whole outlook may be enlarged whilst learning the practice of obstetrics, gynaecology, and pediatrics.

Some reference may be made to the debatable point of the place of systematic lectures, as they have of late fallen somewhat into disrepute, especially in England. A pressed audience is bad for the lecturer and difficult to satisfy, and if attendance on them was not compulsory the prestige of lectures would at once improve. The student would attend without compulsion if he could obtain something he cannot get equally well from his books, and the lecturer would estimate the worth of his lectures by the size of his audience. Systematic lectures have a place if designed to expand and give light and shade to the student's reading by illuminating through clinical experience the lessons taught, and bringing into prominence what is frequently met with and putting into the shade many of the rare and curious scraps from books that often unduly impress the mind of the student. The bearing of anatomical and physiological points on clinical practice can be illustrated and interest aroused on many problems of reproduction affecting the national welfare—heredity and eugenics, the birth rate, child-bed and infantile mortality and invalidity, and the improvement of the national physique—on which guidance from well informed medical opinion may be sought regarding voluntary, municipal, or State schemes of public health.

#### PLANNING THE STUDENT'S COURSE.

Coming now to the actual training to be given, a whole-time minimal period of six months should be allotted to obstetrics, gynaecology, and pediatrics, and early in the first half of this term the student must be in residence for six weeks. A couple of weeks at the beginning of the term may be profitably spent in obtaining a bird's-eye view of the work of the centre as a scheme of preventive medicine, concentrating particularly on the ante-natal clinics and the practice of the maternity wards, and at the same time attending obstetric demonstrations on the dummy. The resident period, as representing the time of most intensive training, should be taken early and the hospital method of delivery and management of the lying-in mother and infant acquired under supervision. Maternity beds, either in a lying-in ward in a general hospital or in a lying-in hospital, must be of sufficient number to allow each student a minimum of five deliveries and to train him in the management of normal and abnormal pregnancy and labour and of the lying-in mother and infant. Obviously, the number of beds must correspond with the number of students trained, but if during his term of residence the average number of deliveries is less than one a day, it cannot be said that the student is really working in an obstetric atmosphere. As pointed out by a committee of the Obstetric Section of the Royal Society of Medicine in 1919, the system of staffing maternity hospitals in England and Scotland militates against efficiency in the teaching of difficult and complicated labour, as a visiting staff does not permit of the continued presence of an experienced teacher throughout a prolonged case; that committee advocated the union of small into large institutions, with at least 75 beds and a resident chief of the standing of the Master of the Rotunda in Dublin. From the educational point of view the Rotunda system presents obvious advantages, but the rearrangement and rebuilding that its introduction into England and Scotland

would entail are almost impossible under present financial conditions. The centralization and amalgamation of existing institutions would appear more feasible in provincial schools, where there is a University that can exert pressure on its constituent teaching institutions, than in London, where the inherent tendency of each medical school to remain self-contained and self-sufficient is difficult to overcome in the absence of a central co-ordinating authority. Oxford and Cambridge did much to further the teaching of midwifery in London by their immediate and whole-hearted adoption of the recommendations of the General Medical Council (1906) insisting on hospital practice, whereby the medical schools were compelled to open lying-in wards or otherwise make provision for the training of those of their students proceeding to a medical degree at the old Universities, such facilities becoming available for all. A still greater advance could be made if, by a combination of the London schools into three or four obstetrical centres and amalgamation with lying-in hospitals, large institutions on the Rotunda model could be inaugurated. Such reorganization would assist in getting over another difficulty, the shortage of cases owing to the number taken up for the training of midwives, in regard to which the regulations of the Central Midwives Board are much more strictly drawn than those of the medical qualifying bodies.

#### THE LYING-IN WARD AND THE DISTRICT.

While urging further and better training, the most must be made of the material at present available, and the management of labour and lying-in, as conducted in hospital, acquired under the supervision of a teacher, first by watching cases delivered by other students and then by personally conducting deliveries. In one hospital the management of normal labour may be taught by the sister-midwife in charge of the labour room, at another by a house officer, at another perhaps an obstetric tutor or registrar, but never by a member of the visiting staff. My personal feeling is strongly in favour of a sister-midwife; she is much to be preferred to a temporary house officer, and the student, who in after-life will have to supervise and assist midwives, had best begin by learning the conduct of normal labour as the midwives do and of abnormal labour from his medical teachers. My chief contention in favour of this plan is that it is the logical sequence of the fundamental principle of the physiological character of labour, which must ever be impressed on the student; normal labour can be left to the midwife, as the nursing of the lying-in mother and infant is left, the function of the medical attendant being the careful supervision before, during, and after labour, but not necessarily entailing his constant presence throughout labour or at the moment of birth. Even in a hospital with an experienced resident chief it would be ridiculous and wasteful excess if the steam-hammer was used to crack nuts.

After a month's experience of hospital midwifery and having acquired thoroughly the hospital routine, the student's education should be completed by learning how to apply these methods to the more difficult conditions met with in the homes of the women in the district. For district work to be really educative to the student a health visitor or other social worker should select the homes suitable and exclude those wholly unsuited; attendance in houses in which it is impossible to carry out an adequate surgical technique only results in discouraging the student and encouraging slovenly methods. The obstetrical registrar or house officer should closely supervise the student's work, making occasional visits with him and seeing that daily reports are presented of all the patients under his charge. Under satisfactory conditions the work on the district is most valuable; for the first time the student is brought into touch with patients in their own homes, where he has an opportunity of seeing the conditions under which they live, how poverty, housing conditions, and lack of education and training in the mother may affect the health of herself and her children, of studying social work, and learning how other agencies, public and voluntary, may be called in for assistance, and generally how to work in with the local health authorities and the whole team of health workers. Training in complicated labour and obstetric emergencies is more difficult to obtain because there are few schools

# The Irish Universities.

There are three universities in Ireland, each with a medical faculty. These are the University of Dublin (usually known as Trinity College, Dublin), the Queen's University of Belfast, and the National University of Ireland. The two former are divided among three constituent colleges, situated, one at Cork, another at Galway, and the third in Dublin. Information as to the arrangements for the education of medical students will be found in the section relating to Irish Medical Schools.

## UNIVERSITY OF DUBLIN: TRINITY COLLEGE.

M.D. and M.B. degrees in medicine (M.B. and M.D.), two in surgery (B.Ch. and M.Ch.), two in midwifery (B.A.O. and M.A.O.), and a post-graduate diploma in public health. It also grants a post-graduate diploma in gynaecology and obstetrics, for which one year's study is required. The degrees are granted to those who, having passed the Professional Examination, have also graduated in arts. A candidate for the Final Examination for the M.B., B.Ch., and B.A.O. degrees must be a matriculated student of at least five years' standing. At least three of the five years' medical curriculum must be pursued at the School of Physics of the university. The examinations which students must pass are the Preliminary Scientific, the Intermediate Medical, and the Final. Before admission to any of these examinations students must have completed the courses of study in the subjects involved.

**Preliminary Scientific.**—This covers (a) chemistry, (b) physics, (c) botany and zoology; the three divisions may be taken together or at different times. **Intermediate Medical.**—This is divided into two parts: (a) anatomy, physiology, organic chemistry, and histology; (b) applied anatomy and applied physiology. The two parts may be taken separately or together. **Final Examination.**—Part I: Hygiene and medical jurisprudence, pathology and bacteriology, materia medica, and therapeutics. Part II: (a) Midwifery and gynaecology; (b) medicine and mental diseases; (c) surgery in all branches, including clinical ophthalmology. The three sections of Part II may be taken separately or together. In either case the full curriculum must have been completed, and the final examination cannot be completed before the end of the fifth year.

**M.D.**—The candidate must have passed all the qualifying examinations in medicine, surgery, and midwifery, and have two years' standing in the degree of B.A. three years previously. He must send in a thesis for approval. Subsequently the Regius Professor of Physics and an assessor will discuss with him questions connected with the thesis, and may also examine him viva voce on other medical subjects of a more general nature. **M.Ch.**—The candidate must be a B.Ch. of not less than three years' standing, and have been engaged in practice for two years. **M.F.O.**—The candidate must be a B.A.O. of not less than two years' standing and must produce satisfactory evidence of having been engaged for two years in obstetric science. The examination is specially directed to obstetrics and practical gynaecology.

**Dental Degrees.**—The University of Dublin gives two degrees in dental science—namely, B.Dent.Sc. and M.Dent.Sc. The course for the former has a minimum duration of four years; for the latter, five years. Further information regarding courses of instruction, etc., may be obtained from the Registrar of the School of Physics, Trinity College, Dublin.

paid by a candidate for the Membership is £36 15s. The examination is held quarterly, and application for admission to it must be made a month previous to its date. For the Fellowship the candidate must have been a member of the College for at least three years, and, if accepted, pays fees, including £25 stamp duty, amounting altogether to £64 18s. Further details can be obtained on application to the Secretary of the College.

## ROYAL COLLEGE OF SURGEONS OF EDINBURGH.

Licentiatees may be of either sex, and for the Fellowship women are eligible also.

### Licentiate.

As an original qualification the Licence is only granted after fulfilment of the regulations of the Council Board, but as an additional qualification it can be obtained by those already possessed of a registrable qualification in medicine. In this case the candidate has to pass a written, oral, and clinical examination in surgery and surgical anatomy, and may be asked to operate on the dead body.

The fee is £15 15s., of which £10 10s. is returned to unsuccessful candidates. On due cause being shown, a special examination may be granted, the fee being £20, of which £10 is returned to a candidate if he is not approved.

### Fellowship.

Candidates for the Fellowship must be not less than 25 years of age, and have been in the practice or study of their profession subsequent to registration for at least two years, and must hold either a surgical degree from a university recognized for that purpose by the College, or a registrable diploma obtained as the result of an examination which includes surgery as well as medicine and midwifery. Candidates are examined in (a) the principles and practice of surgery, including surgical anatomy, (b) clinical surgery, and (c) one optional subject, which they may choose from among the following: surgical pathology and operative surgery, ophthalmology, laryngology, otology, and rhinology, gynaecology, obstetric surgery, anatomy, and dental surgery and pathology. The examination is written, oral, and clinical or practical. A candidate who desires to be examined must give one month's notice, his application for admission being supported by two Fellows of the College, one of whom must be resident in Edinburgh, or, in default, by testimonials obtained specially for the purpose. Candidates are not allowed to appear more than three times at the examinations. Licentiatees of the College pay £35, and others £45. For further information application should be made to the Clerk of the College, Mr. D. L. Eadie, 49, Lauriston Place, Edinburgh.

## ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

This body possesses two classes—Licentiatees and Fellows. The regulations applying to the former correspond with those respecting candidates for the Licence of the Royal College of Surgeons of Edinburgh. Candidates for the single Licence are examined in surgery (including clinical surgery and surgical anatomy). The fee is £15 15s., and examinations are held quarterly. Candidates for the Fellowship must be qualified medical men of not less than two years' standing and 24 years of age. Candidates approved at this examination are then eligible for election as Fellows. Special regulations are in force for medical practitioners who served in the late war. The Faculty can also elect four Fellows annually without previously submitting them to examination, providing they "have highly distinguished themselves in medical science or practice." They must be of not less than ten years' standing and 40 years of age. Further information can be obtained from Mr. Walter Hurst, Faculty Hall, 242, St. Vincent Street, Glasgow.

the student and his advisers should endeavour to obtain a clear idea of the object to be aimed at, of the relative advantages of taking one or other of the degrees or diplomas open to him, and of the comparative difficulties they present.

All who wish to enter the medical profession must comply with certain conditions. These are prescribed by the General Medical Council, which is a statutory body established under the Medical Acts; a statement of its requirements is given at page 355. It will be observed that many changes have lately been made in the medical curriculum, and this section should be studied with care. Every medical student, after passing examinations in the subjects of general education and in the preliminary sciences, must take a course of training at a recognized medical school, covering at least a period of five years but usually extended to six years or more. The examination of candidates as to their fitness to practise medicine is left to the licensing bodies, which are of two kinds—the universities, and certain corporations in England, Scotland, and Ireland. One of the functions of the General Medical Council is to make sure that the tests at each stage do not fall below a certain standard, and that the students examined have undergone prescribed courses of instruction at recognized institutions. Successful candidates at such examinations eventually receive from the body holding them either degrees, in the case of a university, or diplomas or licences, in the case of a corporation; these qualifications entitle them to claim insertion of their names in the *Medical Register* kept by the General Medical Council. Holders of diplomas and licences once made up the great majority of all medical men, especially in England and Wales. But universities have greatly multiplied, and so many practitioners are now graduates that a student of ordinary ability will be well advised to aim at a medical degree, though it may be desirable to take also a diploma or licence.

#### COST OF MEDICAL EDUCATION.

At this point the question of the cost of a medical training naturally arises. The answer, however, cannot possibly be given in a single precise statement, because the outlay varies within wide limits. Besides differences in the charges made by medical schools for instruction there are differences in examination fees, as well as in those payable for the certificates of qualification. Again, not all students, however industrious, pass examinations with equal facility. Since in any case professional education must continue for five years at least (a period exceeded by the vast majority), and since the cost of living in different parts of the country varies much, while personal expenditure varies still more, it can only be said in a general way that anyone who thinks of entering the profession must assume that a medical education—first and last—will cost at least £1,500. On the other hand, the number of scholarships and prizes now offered is larger than in the past; in the Scottish universities bursaries are numerous, and the Carnegie Trust gives financial assistance to many Scottish students. It will be seen, however, that, as compared with other professions, the period of training in medicine is long, and for most students costly. There is also to be remembered the time of waiting after qualification when income is apt to lag behind expenditure.

#### CHOICE OF A CAREER IN MEDICINE.

The student, having passed all his tests and placed his name on the *Medical Register*, becomes a member of the profession and assumes the privileges and responsibilities that go with legal qualification. But the final examination, though a great event in his life, is only the opening of a door into a wider field of training. Education must continue throughout his career; a good doctor remains

always a student. As an introduction to practice nothing is so useful to the newly qualified man or woman as a year or more spent in junior hospital appointments; and all who can afford the time should look upon an "internship" as a most valuable investment. Next comes the choice of a career in the larger world of medicine. Many paths are now open—for example, general practice, Government service at home or abroad, and special work in public health or mental disorder, in scientific research, or in one of the many modern subdivisions of medicine and surgery. Most of these different paths in medicine are considered in some detail in the later sections of the Educational Number, but a few words may be said here about general practice and the work of a consultant or specialist. A good deal of information on these and other cognate matters will be found in the *Handbook for Recently Qualified Medical Practitioners*, published by the British Medical Association.<sup>1</sup>

#### GENERAL PRACTICE.

General practice is still the goal of the great majority of all medical students, and it is beyond question that this country produces the finest body of general practitioners in the world. The life is onerous and exacting; a recent writer has said: "Of all professional men, the general practitioner is the worst paid and the hardest worked." Nevertheless, general practice has its compensations, and it appeals to many of the very best students; which is fortunate, both for medicine and for the public. This career is usually entered upon in one of three ways. The newcomer may take a house and wait for patients to seek his services; he may purchase the goodwill of a practice rendered vacant by retirement or death; or—perhaps best of all—he may become a partner in an established practice. Success in the work of a private practitioner demands, however, a great deal of knowledge other than that gained at the medical schools, and consequently a man is more likely to be accepted as a partner, or to succeed on his own account, if he has already some experience of family practice as an assistant or deputy. An all-round knowledge of practical medicine, surgery, and obstetrics should, if possible, be supplemented by skill in some particular branch of practice. Moreover (as already hinted), the value to a general practitioner of having held one or more resident hospital posts is incalculable. "In after-life," writes Sir William Macewen, "one can generally pick out those who have been thus trained, as they gain a confidence and reliance and experience which they cannot easily obtain elsewhere."

#### CONSULTANTS AND SPECIALISTS.

As for those whose aim it is to become a consultant or specialist, their path, though full of interest, is seldom smooth. For their success will depend in the long run not only upon mental gifts and capacity for hard work, but (as is true of practitioners of all branches) on the possession of those qualities which inspire confidence both in patients and in colleagues. As Sir Clifford Allbutt has well said: "In practice, personal tact and character are as important to the operations of a physician as scientific equipment." Moreover, since the consultant or the specialist can scarcely hope at first to pay his way by consulting work or by the practice of his specialty, he must either have the means to support himself for an uncertain period or be prepared by teaching or in other ways to defray expenses; a hospital appointment is almost indispensable. The question of additional degrees and diplomas is of special moment to those whose ideas turn

<sup>1</sup> *Handbook for Recently Qualified Medical Practitioners*. 1923. British Medical Association, 429, Strand, W.C.2. 2s. 6d. net.

<sup>2</sup> *An Index to General Practice*. By A. Campbell Stark, M.B. 1922. Baillière, Tindall and Cox. 5s. net.

In Midwifery practitioners of over five years' standing are exempted from examination by printed questions. The other grades of the College are Members and Fellows. The former are admitted after an examination which is open to all un-Royal Colleges of Physicians, and deals with the general subjects of medicine. Fellows are selected, by vote, from among the Members of the College, irrespective of sex.

*Fees*.—For the Licence in Medicine, 15 guineas; Special Examination, 10 guineas. For the Membership, 20 guineas to a Licence of the College, 35 guineas to others; a special examination costs 10 guineas extra. The Fellowship, £23, in addition to stamp duty, £23.

Information as to special examinations and other matters can be obtained from the Registrar, the Royal College of Physicians, Kilbare Street, Dublin.

## ROYAL COLLEGE OF SURGEONS IN IRELAND.

This body, besides granting a Licence in Surgery, admits those possessed of registrable surgical qualifications to its Fellowship under certain conditions. Its Licence is usually granted conjointly with that of the College of Physicians, but it is given separately to holders of a registrable qualification in medicine, provided the College is satisfied that adequate courses of study have been pursued, and provided its own provisional examination is passed. This examination is held on its behalf by the Conjoint Board, and is identical with the ordinary surgical portion of the examinations imposed by that body.

*The Fellowship*.—Candidates for the Fellowship must pass two examinations, of which the first is in anatomy (including dissections), physiology, and histology; and the second in surgery (including surgical anatomy) and pathology. Both examinations are partly written, partly practical, and partly viva voce; while the final examination includes the performance of operations. All subjects of either examination must be passed at one time, and to neither can a candidate be admitted who has been rejected in any of its subjects by any other licensing body within three months. Candidates are not admitted to the Primary Examination except on evidence that they have already passed an examination in anatomy, physiology, and histology, held by some university or other body whose degrees or licences entitle the holder to admission to the *Medical Register*; if, however, the candidate's name is on the Colonial or Foreign List in the *Medical Register*, at the discretion of the Council. Candidates for the Final Examination must be over 25 years of age, produce a certificate of general good conduct signed by two or more Fellows of the College, and, if successful, must make a declaration before admission to the effect that they do not conduct dispensing practices, and will not do so as long as they are Fellows.

*Fees*.—Candidates for the Licence pay 5 guineas for examination, which sum, if they pass, is counted as part of the fee payable on admission to the Licence, this being 25 guineas. Candidates for the Fellowship pay 5 guineas for each examination, the total of 10 guineas being reckoned as part of the fee payable on admission to the Fellowship. That fee is 25 guineas in the case of those who are already Licentiates, and 40 guineas in the case of others.

## APOTHECARIES' HALL OF IRELAND.

A diploma is granted by this Hall which entitles the holder to be registered as a practitioner of medicine, surgery, and midwifery, and confers also the privileges of an apothecary. Two periods of dissection, each not less than six months, must be included, and twenty-seven months of hospital attendance, or its equivalent. Three professional examinations have to be passed; they are held three times a year. The Primary Examination deals with biology, physics, and chemistry, practical and theoretical; the Intermediate Examination is in practical anatomy and physiology, and histology and materia medica. A candidate who has passed tests in any of the subjects of these examinations before another licensing body is exempted from further examinations in such subjects. The Intermediate Examination, Part II, consists of pathology, medical jurisprudence, and hygiene. The

Information as to the fees at each of the various metropolitan medical schools, and the scholarships, prizes, and junior appointments which they offer, will be found in the following pages. The courses they provide are fundamentally the same, and in all of them the arrangements made are such as to meet the requirements of students of every class—of those who are aiming at the diplomas of the English Conjoint Board or the Apothecaries' Society, not less than of those who have London or other university degrees in view. At all, too, special facilities are offered to students who have commenced their professional education at Oxford or Cambridge.

*CLINTON CROSS HOSPITAL.*

This school, with its hospital, is situated in the centre of London, and is easily accessible. Primary and intermediate students attend lectures and practical work at King's College. The final studies are taken in the school and hospital, where systematic lectures, demonstrations, and tutorial classes are arranged to cover all the subjects necessary for the qualifying examinations. Departments are also available for the other final subjects of bacteriology, clinical pathology, materia medica, toxicology, public health, operative surgery, and for a staff of scientific workers and fully equipped laboratories, has been established in the school. Students receive their training in preventive medicine, pathology, and bacteriology here, and are encouraged to undertake research.

Women students are admitted to the school and hospital upon the same terms and conditions as men, and after qualification are eligible for resident hospital appointments. A separate common room and a female attendant are provided, but beyond this no further distinction is made.

The fees are at present under revision. Further information may be obtained on application to the Dean of the Medical School, Charing Cross Hospital, London, W.C.2.

*GUY'S HOSPITAL.*

This hospital contains 626 beds in constant occupation. Twenty-six beds are set apart for diseases of the eye, and 40 for the most urgent and interesting medical cases, which from the subjects of the weekly clinical lectures. There is a special ward of 80 beds for the reception of cases of diseases of women and for cases of difficult labour. Beds are also allotted to the throat and ear departments, the orthopaedic department, the department for the treatment of diseases of the genito-urinary system, and the children's department; there are also some special beds for the treatment of syphilis. The residential college fronts the east gate of the hospital, providing accommodation for resident students. This contains a dining hall, reading rooms, a library of general literature, and a gymnasium for the use of the residents, and of the members of the Clubs Union. The athletic ground at Honor Oak Park is reached from the hospital in twenty minutes. The Gordon Museum of Pathology, the Willis Library, the Departments of Chemistry, Physics, Pathology, and Pharmacology, and the school buildings in general, afford opportunities for a liberal education and for research, and provide the full curriculum for a medical qualification. New departments of Anatomy, Physics, and Biology were opened in July, 1923. They are equipped on modern lines, and provide ample accommodation for teaching and research. Special classes are held for the first and second examinations for medical degrees of the University of London and for the first F.R.C.S. Eng. Special teaching is provided to meet the

## MEDICAL SCHOOLS AND COLLEGES.

Application for other information should be made to the Registrar, 95, Merton Square, Dublin.

*Fees*.—Primary Examination, £10 10s.; Intermediate Examination, £10 10s.; Final Examination, £21. Final alone, when the others have been passed elsewhere, £26 5s.

that medical men and women must band themselves together for the common protection of their profession and themselves. The first step after qualification should be to become an active member of the British Medical Association and to join one of the two professional defence societies. A young practitioner will find in the meetings of the local Division of the British Medical Association many opportunities, not only of keeping abreast with the progress of medicine, but also of friendly intercourse with colleagues.

The Association was founded in 1832 to promote the medical sciences and to maintain the honour and interests of the profession. A brief note on its objects and constitution, and the advantages offered to members, will be found at page 398. The record of ninety years' work shows that professional organization, directed with wisdom and imagination, can successfully combine service for its members with service for the public. Greater work remains to be done in each direction, and we look to the rising generation of doctors to take their share.

### THE NEW ERA IN MEDICAL EDUCATION.

A FULL account of the resolutions and recommendations of the General Medical Council which have applied since the beginning of 1923 is given in the present issue of the JOURNAL. Here we propose to indicate some of the salient features of the new scheme, both of study and of examination.

#### *The Revised Curriculum.*

The minimum age for registration as a medical student has been increased from 16 years to 17 years. Formally, the length of the medical curriculum is not added to; practically it is, by transferring to preliminary study and examination the subjects of elementary physics and chemistry in their purely scientific aspects. In their applications to the professional courses—as in biophysics, biochemistry, and pharmacological chemistry—appropriate instruction is to continue throughout the curriculum, and is to be tested by examination, so that the student shall no longer be able to put behind him as passed and done with the knowledge which he acquired as a preliminary. If he has had no facilities at a secondary school or otherwise for obtaining what is necessary for the preliminary examination in these subjects, then he can come for it to the university or college, but study there will not count for the medical curriculum.

In biology it is understood that comparatively few secondary schools are equipped for elementary tuition, but the Council has suggested an ingenious arrangement for utilizing the work of such schools as are qualified for the purpose. The examination will not be "pre-curriculum," but the instruction may be so, and a licensing body can allow students who so desire to sit for the examination immediately after matriculation. Here again, however, the applications of biology to medicine, surgery, and midwifery will continue to receive attention throughout the courses.

The Council attaches great importance to the reservation of sufficient time for the later subjects of study, free from all worries about passing the examinations of the earlier parts. To that end it recommends what is practically a block system. A minimum of three years should be available, not merely after the courses of anatomy and physiology have been taken, but after the professional examinations have been passed. The value of this proposal is obvious.

#### *Examination Reform.*

Another notable feature is that in assessing marks in the several examinations account may be taken of "duly attested records of the work done by the candidate throughout his course of study" in the subject. This is an effort to meet the long felt difficulty that a man's mental agility, or the want of it, counts far too much in his being passed or rejected. The difficulty is real, but the remedy is not easy, and the Council is wise in the cautious

approach it makes towards a solution. Where, as in the colleges, a student will only by chance come before his own teacher as an examiner, absolute impartiality in the attested records will be necessary. A teacher must not play for popularity with students by too easy certification of diligence or success in class. On the other hand, at the universities, where the teacher is always one of the examiners, no personal like or dislike of a student must influence the report of the internal to the external examiner. The class records should, of course, be available, but the scheme will put a serious ethical obligation on all concerned, and the Council will doubtless watch its operation with keen and critical interest.

Besides the Resolutions of the General Medical Council in regard to professional education and examination (see pages 355-358), a series of additional Resolutions was adopted on May 26th, 1922, as follows:

(a) That throughout the whole period of study the attention of the student should be directed by his teachers to the importance of the preventive aspects of Medicine;

(b) That each Licensing Body should make adequate arrangements for the effective correlation of the several subjects of study throughout its curriculum;

(c) That the teaching of Anatomy and Physiology should include as a regular part of the courses the demonstration on the living human body of structure and function;

(d) That the curriculum should be so arranged that a minimum period of three years shall in every case be available for study after the completion by the student of the Professional Examinations in Anatomy and Physiology held at the close of the second year;

(e) That the curriculum should be so framed as to afford sufficient opportunities for the study, during the last three years of the course, of Physics, Chemistry, Biology, Anatomy, and Physiology in their practical applications to Medicine, Surgery, and Midwifery, and that the student's knowledge of these applications should be subject to test in the Final Examination;

(f) That before the student is admitted to his clinical appointments he should have received practical instruction in clinical methods and in the recognition and interpretation of physical signs;

(g) That instruction should be given, in the courses of Forensic Medicine and Public Health or otherwise, on the duties which devolve upon practitioners in their relation to the State, and on the generally recognized rules of Medical Ethics. Attention should be called to all Notices on these subjects issued by the General Medical Council.

#### *Training in Preventive Medicine.*

The first of these resolutions should be borne in mind by every teacher throughout the whole curriculum, and not merely in the clinical subjects. As indicated in a questionnaire issued by the Council in 1918, all the earlier subjects—Physics, Chemistry, Biology, Physiology, Anatomy, and, of course, Pathology, Bacteriology, and Therapeutics also—afford opportunities from the very beginning for instilling into the mind of the student the necessity for his keeping constantly in view, in all the advice and treatment he may give throughout his professional life, the primary importance of promoting the general health of those who entrust themselves to his care, and of preventing trivial ailments from developing into definite disease. In his presidential address to the Council five years ago Sir Donald MacAlister pointed out that if "the efficient practice of their profession" by doctors was "to be judged by new civic standards, and to be carried on under new conditions," the student would have to be trained accordingly. The era of that training has begun formally this year. Though no details are given in resolution (a), and though it may require some change of orientation by teachers who have hitherto given no special heed to the bearings of their subject on the maintenance of health and the prevention of disease, yet they will doubtless join heartily in what will indeed be an epoch-making advance in medical education in this country. Its reflex and reward will surely be found as time passes in a diminution of sickness and prolongation

the applicant is residing—England and Wales, or Scotland, or Ireland. It must be made on a special form, which can be obtained from one of the offices of the General Medical Council itself or from one of the various licensing bodies and medical schools.

The regulations with regard to registration apply equally to medical and dental students, with the exception that in the case of the latter pupilage with a registered dental practitioner may be regarded as a commencement of professional study, and that applications for registration should be addressed to the London office only.

#### PROFESSIONAL EDUCATION.

The rule is that it is only from the date which appears against his name in the *Students Register* that the medical student's career officially begins; thereafter five years must pass before he can present himself for the final examination for any diploma which entitles its lawful possessor to registration as a qualified medical practitioner under the Medical Acts; but to meet the circumstances brought about by the dates at which sessions of the medical schools begin and end, the close of the fifth year may be reckoned as occurring at the expiration of fifty-seven months from the date of registration. In any case, the period of five years must be one of bona fide study, and in every course the following subjects should be included:

- (i) Elements of General Biology, including an introduction to Embryology. This course, if the Licensing Bodies permit, may be taken before registration, and the examination may be passed immediately after registration.
- (ii) Chemistry, Physics, and Biology in their application to Medicine.
- (iii) Human Anatomy and Physiology, including Histology, Elements of Embryology, Biochemistry, and Biophysics.
- (iv) Elementary Bacteriology, prior to regular clinical appointments.
- (v) Pathology general, special, and clinical, and Morbid Anatomy.
- (vi) Pharmacology and Materia Medica, to be taken concurrently with clinical instruction.
- (vii) Forensic Medicine, Hygiene, and Public Health.
- (viii) Medicine, including applied Anatomy and Physiology, Clinical Pathology and Therapeutics, Children's Diseases, Acute Infectious Diseases, Tuberculosis, Mental Diseases, Skin Diseases, and Vaccination.
- (ix) Surgery, including applied Anatomy and Physiology and Clinical Pathology, Anaesthetics, Diseases of the Eye, Ear, Throat and Nose, Radiology, Venereal Diseases, and Orthopaedics.
- (x) Midwifery and Diseases of Women, including ante-natal conditions and infant hygiene.

The Council recommends that during the last three of the five academic years clinical subjects shall be studied.

The first two years must be passed at a school of medicine recognized by any of the licensing bodies enumerated in the schedule to the Medical Act of 1858, and the remainder must be devoted to clinical work at any public hospital or dispensary at home or abroad which is recognized by a licensing body.

#### SPECIAL CONSIDERATIONS.

The requirements of the General Medical Council in respect of the education of those who desire to enter the medical profession have now been given in outline, but before leaving this part of the subject the steps which the aspirant should take may be rehearsed in their due order:

- (1) Pass an examination in arts;
- (2) Pass an examination conducted or recognized by a licensing body in elementary physics and elementary chemistry.
- (3) Enter himself at a medical school or other scientific institution approved by the Council;
- (4) Get himself registered as a medical student;
- (5) Study for a minimum of five years certain prescribed subjects;
- (6) Meanwhile pass sundry intermediate examinations; and at the end of the fifth year pass a "qualifying examination" which will entitle him to receive from a licensing body a legal authority to practise.

*The Minimum Period.*—It must be remembered that the period of five years is a minimum; more is often required even by the man of good abilities and reasonable industry. Besides these qualities a student, to obtain a registrable qualification in the minimum period of five years, or fifty-seven months, must have a considerable amount of good luck; in other words, he must keep in good health through every term, and never fail at a single examination. Thus,

for instance, before presenting himself for any examination he must be "signed up" for the subjects covered by the examination; this means that his teachers have to certify that he has diligently attended the required number of lectures or classes in the subjects in question. If, however, the student happens to be ill during the term when such lectures or classes are taking place he may miss enough of them to make it impossible for him to be signed up. Then, again, should he fail to satisfy the examiners at some examination, he cannot present himself for re-examination for at least three months. This generally entails further consequences, because, apart from the student's success at the next stage in his career being imperilled by the need for restudying the subjects in which he has failed, the Examining Boards usually insist upon a definite interval elapsing between one examination and the next. Further, many Boards have refused to recognize lectures and classes which have been attended before the student has passed the requisite examination in earlier subjects, and the Council now recommends that the professional examinations in anatomy and physiology be passed before the minimum period of three years' subsequent study be entered on. In other words, no clinical study should count as such until these examinations have been successfully completed. Failure at an examination may thus not only mean deferment of the date of examinations, but deferment of the beginning of the student's study of certain subjects. It is thus exceedingly easy for a student to fail to qualify in five years, and, as a fact, the majority of students take longer.

In speaking of the minimum period, it is to be remembered also that that time is only sufficient to gain a registrable qualification, such as a Bachelorship of Medicine or Surgery or the diplomas of the Royal Colleges. Those who wish to take a higher qualification—for instance, the F.R.C.S. Eng.—must prolong their work for another year or more. So, too, must in some cases those who desire to convert their Bachelorship into a Doctorate. This may entail further formal examination, but at some universities the M.D. is obtainable on presentation of a thesis when the Bachelor has attained a certain age and has practised for a certain number of years. However, a student's career proper may be considered, perhaps, to have ended when he obtains his first registrable qualification, for while preparing himself for any further tests he can, and usually does, hold some junior appointment which more or less covers his expenses.

#### MEMORANDUM ON STUDENTS' REGISTRATION.

The following memorandum has been drawn up by the Registrar of the General Medical Council as to the procedure for those who desire to be registered as medical or dental students.

The requirements for the registration of medical and dental students are the same, and every intending student should, in his own interest, register as soon as he commences his professional curriculum.

A recognized examination in general education must first be passed. If the student intends to obtain a university degree, he should apply to the university he selects for information as to its matriculation requirements in arts or pure science, or as to any examinations which may be accepted in lieu of its matriculation examination. If the student intends to obtain a qualification from one of the licensing corporations (these are the Conjoint Boards in England, Scotland, and Ireland, the Society of Apothecaries of London, and the Apothecaries' Hall of Dublin), any of the examinations indicated below will be accepted. The subjects required are (1) English, (2) Mathematics (elementary), (3) a language other than English, and (4) an additional subject or subjects, as required by the regulations of the particular examination, to be chosen from the following—namely, History, Geography, Physical Science, Natural Science, Latin, Greek, Hebrew, French, German, or other language accepted by the university for matriculation.

The requirements of the preliminary examination in general education being satisfied, it is then necessary to pass an examination in Elementary Chemistry and Elementary Physics, which is conducted or recognized by one of the licensing bodies—that is, the university or corporation. The student should write to the body whose qualification he desires to obtain (a list will be found below) for information in regard to its requirements for the examination.

These two examinations having been passed and the student having attained the age of 17 years, he should apply to one of the universities or one of the medical schools for admission in

The school thus provides the final course of study for the graduates of the Universities of London, Oxford, Cambridge, Durham, and other British universities, and for the diploma of the Royal College of Physicians and Surgeons in Medicine and Dental Surgery, and the Licence of the Society of Apothecaries. Special bacteriological classes are also held in preparation for the various diplomas of public health. Each department is also equipped for more advanced work, and provides

must be presented to the examiners for assessment in the Final Examination; and no candidate should be allowed to pass who fails to obtain 50 per cent. of the aggregate marks assigned to Clinical and Practical Midwifery and Gynaecology.

19. The Final Examination should include the examination of secretions, the testing of urine, clinical microscopy, and prescription writing, and there should always be an oral examination in Medicine, Surgery, and Midwifery, which should include an examination on pathological specimens.

20. At the Final Examination each candidate should be submitted to a practical and oral examination in Pathology (macroscopic and microscopic), unless this has been included in a Professional Examination preceding the Final Examination.

21. Whatever be the method of entry for the Final Examination all candidates should be required to complete the three portions of the Final Examination within a period of nineteen months.

## The English Universities.

THERE are eleven universities in England and Wales, and some account of each of them follows. They all have now fully developed medical faculties. Until recently the only exception was the University of Wales, whose constituent colleges are those of Aberystwyth, Bangor, Cardiff, and Swansea. This university grants degrees, and has laid down a six years' curriculum for candidates for the M.B. and B.Ch. degrees, and it now provides, at the Welsh National School of Medicine at Cardiff (see page 361), instruction in all the subjects of the medical curriculum.

### UNIVERSITY OF OXFORD.

The professional degrees conferred by this university are those of Bachelor of Medicine (B.M.), Bachelor of Surgery (B.Ch.), Doctor of Medicine (D.M.), and Master of Surgery (M.Ch.). It also grants a diploma in Public Health and a diploma in Ophthalmology. On receiving the B.M. the candidate is entitled to registration by the General Medical Council. In favourable circumstances this degree and the B.Ch. may be obtained in six or seven years from matriculation. Before receiving either, the candidate must have taken a degree in Arts (B.A.), for which three years' residence within the university is necessary. This, however, does not necessarily mean deferment of professional study for that period, for some of the subjects chosen for the final stage of the arts course may be the same as those in which examinations would in any case have to be passed for the medical degrees.

In accordance with a statute which came into force on October 7th, 1920, women may be matriculated and admitted to degrees in the university. The statute is retrospective under certain conditions. Before matriculation a woman must have been admitted as a member of one of the five societies of women students (Lady Margaret Hall, Somerville College, St. Hugh's College, St. Hilda's Hall, or the Society of Oxford Home Students). Women members of the university are admitted to all degrees, except those in Divinity, under the same conditions as those laid down for men in regard to examinations, courses of study, and fees, and under corresponding conditions as to residence at the university. Among the university diplomas open to women are those in anthropology, ophthalmology, and public health.

A candidate may obtain the B.A. degree in either of the following ways, of which the latter constitutes the normal course for medical students:

(a) By passing Responsions (or one of the examinations which are accepted as equivalent), Moderations, a Scripture examination, or, in the event of a candidate objecting, an examination on some substituted book; and the Final Pass School in three subjects, two of which may be the same as two of the preliminary examinations in natural science.<sup>1</sup>

(b) By passing Responsions, the Scripture examination, some of the preliminary examinations in the Natural Science School,<sup>2</sup> or the Honour School of Mathematics in the first public examination; and one of the final honour examinations. The Final Honour School of Natural Science (Physiology) is that usually taken.

<sup>1</sup> The four subjects of the medical preliminary examinations are four of the subjects in the natural science preliminary, and can be commenced directly after passing Responsions.

Responsions and the preliminary examinations in Natural Science may be passed before a candidate is a member of the university<sup>3</sup>; Moderations and Scripture can be passed in or after the second term; the final pass school may be taken any time after Moderations; a final honour school may be taken at the end of the third or fourth academical year—that is, within nine or twelve terms respectively; the preliminary examinations of the Natural Science School may be taken as soon as Responsions have been passed.

### PROFESSIONAL DEGREES.

To obtain the B.M., B.Ch. degrees the candidate must first pass in four of the subjects of the Preliminary Examination of the Natural Science School—namely, physics, chemistry, zoology, and botany.

He then has two further examinations to pass—the First B.M. and the Second B.M. These take place twice a year, the first on the Thursday, the second on the Wednesday, of the eighth week of Michaelmas and Trinity terms. Every candidate at the First B.M. is examined in human anatomy, in physiology, and in organic chemistry, but is excused from physiology if he has obtained a first or second class in the Honour School of Physiology, and from organic chemistry if he has satisfied the Examiners in Part I of the Honour School of Chemistry. Once he has passed this examination he can, on production of certain certificates, be examined as soon as he pleases in pathology, forensic medicine, and hygiene, materia medica, and pharmacology (subjects of the second examination), but cannot present himself for the remaining subjects—medicine, surgery, and midwifery—until the eighteenth term from the day of his matriculation, and not until a period of at least twenty-two months has elapsed from the date of his passing the first examination,<sup>2</sup> and he must take all the three subjects at one and the same time.

Before admission to the second B.M. examination the student must produce certificates of instruction from a medical school recognized by the university of having acted as clinical clerk and dresser, each for six months, and as *post-mortem* clerk for three months, of attendance on labours, of instruction in infectious and mental diseases and ophthalmology, and of proficiency in vaccination and the administration of anaesthetics.<sup>3</sup> He must also produce certificates of attendance in laboratory courses in pathology, bacteriology, and pharmacology, either in Oxford or in a recognized medical school.

### D.M. AND M.CH. DEGREES.

A Bachelor of Medicine who wishes to proceed to the D.M. must have entered his thirtieth term and must present a dissertation for approval by the appointed examiners on a subject previously approved by the Regius Professor of Medicine. If a candidate for the M.Ch. he must have entered his twenty-first term and must pass an examination, which is held in June.

Examinations for the Diploma in Public Health are held in Trinity and Michaelmas terms; that for the Diploma in Ophthalmology is held annually, commencing on the third Monday in July. For the Diploma of Ophthalmology attendance on a twelve months' course of clinical ophthalmology in hospitals or institutions recognized for the purpose by the Board of the Faculty of Medicine, and on a course of instruction in Oxford lasting two months, is obligatory. Candidates must have their names on the *Medical Register* of the United Kingdom, unless, being Bachelors or Doctors of Medicine of universities outside the United Kingdom, they have obtained special permission from the Board of the Faculty of Medicine.

### TEACHING.

The several colleges provide their undergraduate members with tutors for all examinations up to the B.A. degree. In addition, the university provides certain courses of instruction, including lectures, demonstrations, and practical work, which cover all the subjects of the Preliminary Examination and First B.M., and in part those of the Final Examination.

<sup>1</sup> Membership is constituted by matriculation and by becoming either a member of a College or a Hall or a non-collegiate student.

<sup>2</sup> For students commencing medical study after December 31st, 1922, this period will be thirty-three months.

<sup>3</sup> For the certificates that will be required from candidates amenable to the new Regulations of the General Medical Council, see *Examination Statutes*, Clarendon Press, Oxford, 1923 edition (in the press).

take the London Conjoint diplomas before graduating in medicine and surgery at their own university.

#### BIRMINGHAM.

This school in this city is carried on by the Medical Faculty of the University of Birmingham, its students having an adequate number of good laboratories, classrooms, and other necessities devoted to their use by the university. The clinical work is done at the General and Queen's Hospitals, which are amalgamated for this purpose. Together they have upwards of 600 beds for medical, surgical, and special cases, including one for lying-in women. Clinical instruction is given in the wards and out-patient and special departments daily, and formal clinical lectures delivered weekly throughout the winter and summer sessions. Special tutorial classes are also held alike for the degrees of Birmingham and some other universities and for the diplomas of corporations.

**Appointments.**—The large number of appointments open to past or other students includes the following:—At the General Hospital: surgical registrar, £200 a year; one resident medical officer, salary £155 a year; one resident surgical officer, salary £180 a year; one resident pathologist, salary £70 a year; two visiting anaesthetists, salary £50 a year; four house-surgeons, office tenable for nine months, £70 a year; one house-surgeon to the gynaecological and one to the special departments, each tenable for six months, £70 a year; At the Queen's Hospital: three house-physicians, £70 a year; three house-physicians, post tenable for six months, £70 a year; one house-surgeon to the general department, £70 a year; one house-surgeon to the gynaecological and one to the special departments, each tenable for six months, £70 a year; At the Birmingham General and Branch Dispensaries: twelve resident surgeons. At the Birmingham General and Branch Dispensaries: five assistant medical officers. At the City Fever Hospital: three assistant medical officers. At the Children's Hospital: one resident surgical officer, one resident medical officer. At the Birmingham and Midland Eye Hospital: four resident surgeons. At the Orthopaedic and Spinal Hospital: two clinical assistants (non-resident). At the Ear and Throat Hospital: one house-surgeon, £70 a year; four clinical assistants (non-resident). Four non-resident Poor Law appointments are in the gift of the Board of Guardians.

**Scholarships.**—There are numerous money and other awards for students of suitable merit, among them being the following: The Walter Myers Travelling Studentship of £300, offered in 1931, and in each alternate year succeeding, tenable at home or abroad; the Sands-Cox Scholarship of £42 (an entrance scholarship in the Faculty of Medicine, awarded on either matriculation or First M.B. marks); four Queen's Scholarships of £10 each, awarded annually at the second, third, fourth, and final university examinations respectively; one or more Sydenham Scholarships, allotted on entrance to students who are the sons of deceased medical men; the Langley Scholarships (two) of £10 for proficiency in midwifery and diseases of women; the Arthur Foxwell Memorial Gold Medal (Clinical Medicine) at Final M.B. examination. There is also an annual surgical prize, awarded to students proceeding to a degree in dental surgery. University Clinical Board Prizes are awarded to students as follows: Senior Medical prize, Gold Medal; Senior Surgical prize, Gold Medal; Midwifery prize, Gold Medal; Junior Medical prize, Silver Medal; Junior Surgical prize, Silver Medal.

**Fees.**—The composition fee for university classes is £100 5s. This covers all the work required for the degrees of Birmingham and some other universities, and for the ordinary qualifications required for the Fellowship of the Royal College of Surgeons of England, the diploma and degrees of the university in State Medicine, and some including hospital and examination fees, is estimated at £197 0s. 6d. Other information should be sought from the Dean of the Medical Faculty, University, Edmund Street, Birmingham.

#### UNIVERSITY COLLEGE.

This institution, one of the principal component parts of the University of London, possesses a Faculty of Medical Sciences whose work covers all the subjects included in the group commonly known as the preliminary medical sciences—namely, physics, chemistry, botany, and zoology; and also the intermediate medical sciences—namely, anatomy, physiology, and pharmacology. The new anatomy building, provided by the munificent gift of the Rockefeller Foundation of New York, was opened on May 31st, 1923, by His Majesty the King. This building forms part of the block which includes physiology and pharmacology. The Department of Hygiene and Public Health prepares for the diplomas in public health of the Royal Colleges and of the various universities. Research work is undertaken in all the above named departments. The College undertakes the education of students in all the subjects mentioned, leaving them free to complete their education in the strictly professional subjects—medicine, surgery, and the like—at any one of the recognized schools of advanced medical studies. The work is somewhat differently arranged, according to whether the student has in view the degrees of the University of London or the diplomas of the Royal Colleges. In either case the whole work to be done is divided into courses devised to meet the requirements of different examinations, and students can join the College for any of them. Women students are admitted to all courses on the same terms as men. The general arrangements for the benefit of students include membership of the Union Society or the Women's Union Society with the College gymnasium and the athletic grounds. There is also a collegiate residence for about fifty-five men students at Ealing, and for about seventy women students at Byng Place, Gordon Square.

**Scholarships.**—The scholarships and exhibitions obtainable include the Bucknill Scholarships, value 155 guineas, in chemistry, physics, botany, and zoology (the successful student must complete his work at University College Hospital Medical School); and two entrance exhibitions in the same subjects, each of the value of 55 guineas. **Fees.**—The fees for the courses covering the work of the First Examination for medical degrees of the University of London, and in both parts of the Second Examination, amount to 115 guineas. The fees for the courses covering the corresponding examinations held by the Conjoint Board in England also amount to 115 guineas. These fees may be divided into payments for the different courses more than a stated period.

A handbook specially relating to this faculty may be obtained on application to the Secretary of University College, Gower Street, London, W.C.1.

#### THE PROVINCES.

There are in England and Wales, not counting London, ten medical schools, each supplying instruction in the full medical curriculum. Accounts of them here follow. In several cases there is appended information concerning hospitals other than those directly connected with the school, in question; such hospitals, officially and unofficially, play a part in the education which the students of the school receive, and in any case serve as places of additional or post-graduate study.

#### OXFORD AND CAMBRIDGE.

Born at Oxford and Cambridge there are medical schools which furnish unsurpassed opportunities for obtaining a good knowledge of the preliminary sciences and of anatomy, physiology, and pathology. The laboratories are excellently furnished, and the teaching staffs most distinguished. Both schools provide a full medical curriculum, and there is no essential reason why the student should not complete his career at either of them, but this is not commonly done. The local hospitals, though well equipped, are comparatively small. The university authorities therefore encourage the students, as soon as they have completed the earlier examinations and taken a degree in Arts, to join some London school, and thus spend the time of their preparation for the final examinations in a city where the opportunities for gaining clinical knowledge are greater and more varied. A considerable proportion of Oxford and Cambridge medical students

other way; and, unless they are already registered medical practitioners of a certain age and standing, all students must pass not less than five and a half years in professional study subsequent to matriculation.

#### PROFESSIONAL EXAMINATIONS.

**M.B., B.S.**—There are three examinations, the last two being subdivided. They are held twice a year.

The First Examination covers inorganic chemistry, general biology, and physics, there being two papers, a practical test, and a possible oral test in each subject. The names of successful candidates are placed in alphabetical order, with a note as to any subject in which a candidate has distinguished himself or herself.

The Second Examination, Part I, cannot be passed within six months of the passing of the First Examination. It covers organic and applied chemistry, the candidate's knowledge being tested as in the earlier examination. It is a pass examination, but a mark of distinction may be won. Candidates for Part II must have passed the First Examination at least eighteen months previously, besides having completed Part I of the Second Examination. The subjects are anatomy, physiology, and pharmacology, the tests being written, oral, and practical. Candidates who fail in one subject may sit for re-examination in that subject alone if the examiners think fit.

No candidate is admitted to the Third M.B., B.S. Examination within three academic years from the date of his completing the Second Examination. The subjects are medicine (including therapeutics and mental diseases), pathology, forensic medicine and hygiene, surgery, and midwifery and diseases of women. They may be divided into two groups, one comprising medicine, pathology, forensic medicine, and hygiene, and the other surgery and midwifery and diseases of women. Either group may be taken first at the option of the candidate, or the groups may be taken together. Only candidates who show a competent knowledge of all the subjects comprising a group are passed. There is no separate examination held for honours, but the names of successful candidates are divided into an honours list and a pass list, and a university medal may be awarded the candidate who has most distinguished himself in the whole examination.

#### THE HIGHER DEGREES.

**M.D.**—An examination for the M.D. is held twice yearly—in December and July. Every candidate must have passed the examination for the M.B., B.S., unless he became M.B. before May, 1904. He may present himself for examination in any one of the following branches: (1) Medicine, (2) pathology, (3) mental diseases and psychology, (4) midwifery and diseases of women, (5) State medicine, (6) tropical medicine, and, if he wishes, may pass also in another branch at a subsequent examination.

The period that must elapse between acquiring the M.B. and sitting for the M.D. in any branch varies between one and two years, according to the nature of the candidate's previous work, and in all cases evidence must be afforded of special study of the subject chosen; both written and practical examinations must be passed, though exemptions can be obtained from the former in exceptional circumstances. In each branch the scheme of examination is the same: two papers on its special subject, a paper on an allied subject—for example, medicine in the case of branch (4), pathology in branch (1)—an essay on one of two suggested topics connected with the special subject, and a clinical or other practical test. In any branch of the M.D. Examination a gold medal of the value of £20 may be awarded.

**M.S.**—The regulations with regard to the Mastership in Surgery are of a corresponding kind, but there are only two branches in which it may be obtained—General Surgery and Dental Surgery.

#### FEES.

The examination fees have been raised from pounds to guineas for all examinations held after September 1st, 1918. For Matriculation: 2 guineas for each entry. First Examination: 5 guineas for each entry to the whole examination. For re-examination in one subject the fee is 2 guineas. Second Examination, Part I: 2 guineas for the first and each subsequent entry. Second Examination, Part II: 8 guineas for each entry to the whole examination. For re-examination in one subject the fee is 4 guineas. M.B., B.S.

Examination: 10 guineas for each entry to the whole examination, and 5 guineas for examination or re-examination in either group. M.D. and M.S. Examinations: 20 guineas, and 10 guineas on re-examination.

Inquiries should be addressed to the Registrar, the University of London, South Kensington, S.W.7.

#### UNIVERSITY OF BIRMINGHAM.

This university confers the ordinary medical and surgical degrees—M.B., Ch.B., M.D., and Ch.M.—and also diplomas and degrees in State medicine and dentistry. It has a plan, too, by which, extending his study to six instead of five years, the M.B., Ch.B. candidate may become a Bachelor in Science as well. Of the five years' curriculum, the first four must be spent, as a rule, at the university itself, the fifth being passed at any approved school or schools. Occasionally, however, the Senate will reduce the period of enforced residence to three years and exempt from the First M.B. (Part I) those who have passed elsewhere an examination considered to be its equivalent. A degree of Ph.D. is also conferred for research study in medicine under special regulations. Candidates must be graduates in medicine of a recognized university.

Students entering the Medical Faculty for the M.B., Ch.B. degrees must have passed—

(1) Either (a) the matriculation examination of the Joint Board of the Universities of Manchester, Liverpool, Leeds, Sheffield, and Birmingham; or (b) some other examination recognized as equivalent to the matriculation. Candidates for medical degrees are recommended to take Latin and a science subject—chemistry or physics—at the matriculation examination, although these subjects are no longer compulsory. The matriculation examination of the Joint Board is held in July and September. The regulations and the list of examinations accepted in lieu thereof will be sent on application to the Secretary to the Board, Joint Matriculation Board, 315, Oxford Road, Manchester.

(2) A recognized pre-medical examination in the subjects of chemistry and physics—for example, the Higher School Certificate of the Joint Matriculation Board; or a candidate may attend courses for pre-medical year in the university, October to June, taking chemistry and physics, and biology (optional).

#### PROFESSIONAL EXAMINATIONS.

The candidate for the M.B., Ch.B. degrees has five examinations to pass. In the second and final examinations the candidate must pass in all the prescribed subjects or undergo the whole examination again.

The First M.B. (Part I) deals with elementary biology, and physical and organic chemistry. The First M.B. (Part II) and physical and organic chemistry. The First M.B. (Part II) deals with anatomy and physiology, and the student must pass in both simultaneously. The Second M.B. deals with general pathology and bacteriology, materia medica, and practical pharmacy. The Third M.B. takes place at the end of the fourth year, the subjects being forensic medicine, toxicology, public health, therapeutics, and special pathology.

**Final M.B.**—This comprises medicine, surgery, midwifery and diseases of women, ophthalmology, and mental diseases. The candidate, in addition to more ordinary certificates, must be prepared with a certificate of having acted as a post-mortem clerk for three months, and received special instruction in anaesthetics and clinical instruction in diseases peculiar to women, asylum ward work, ophthalmology, venereal diseases, etc. In respect to ophthalmology he must show that he has learnt refraction work. He also has to present to the examiners reports by himself on six gynaecological cases, and certificates drawn up by himself regarding four actual cases of lunacy and notes on two others.

**M.D.**—An ordinary candidate for this degree must be a M.B., Ch.B., of not less than one year's standing. He presents an original thesis for approval, and then passes a general examination in the principles and practice of medicine. From the latter the Board of Examiners may exempt a candidate whose thesis is of exceptional merit. The regulations respecting the Ch.M. are of the same general character. Subject to certain requirements as to special research or other post-graduate study, graduates of other universities may obtain the M.D. and Ch.M. in the same way as holders of the Birmingham M.B., Ch.B.

*Fees*.—Information as to the fees for the courses of instruction provided by the schools should be sought from the Dean of the ships.

MANCHESTER.

[illegible]

*Entrance and other Scholarships*.—The following are among the scholarships obtainable by students of the school: Rogers and Seaton Scholarships in Arts (in alternate years), £40 per annum for two years. Arty Entrance Scholarship in Mathematics, £25 per annum, value £25, one being awarded annually, except in such years as a Cartwright Scholarship is awarded. Cartwright Scholarship, £35 per annum, tenable for three years. Three tuition Scholarships, tenable for three years, of £35, one being awarded annually for proficiency in subjects of general education. Two James Gassill Scholarships of £25, tenable for two years, one being awarded annually for proficiency in the branches of mechanics and chemistry. A Dorr Miter Scholarship, £30 per annum, tenable for three years, and open to the competition of women students only. This is awarded triennially. Sir J. P. Kay-Schuttenworth Scholarship, £30 per annum, tenable for three years, awarded triennially, open to the competition of scholars from Seaford School, Giggleswick School, and Burnley Grammar School. Subjects: mathematics, chemistry, and mechanics. Dreshfield Memorial Scholarship, value £20, tenable for two years and awarded triennially on the result of the Entrance Examination. A Theodosius Moxon Medical Scholarships, value £45 and £25, tenable for one year, for candidates who have not commenced the second year of study leading to a medical qualification. Subjects: zoology, botany, and anatomy.

The fees—It is estimated by the authorities that the approximate cost of medical education to a student in this university is £3'000, plus, of course, the expenses of living during the five years covered by the curriculum. The fee for a complete course for the first three examinations, and for the clinical work at the infirmary, is £151. The composition and fee for the second and third examinations, and for the clinical work at the infirmary, is £174. The composition and fee for the second and third examinations is £133.

The analysis, which are covered by the composition fee, the university does not charge parents or students for the results of the examination, of the value of \$68, in the form of a free admission.

[illegible]

years, two at least of such years having been passed in the university, at least one year being subsequent to the date of passing the first examination. They must also have matriculated by satisfying the examiners in:

- I. *Either English Composition and English Literature, or English Composition and History.*
- II. *Either Mathematics or Latin.*
- III. } *Three other subjects not already taken under I and II above,*
- IV. } *chosen from the following list:*
- V. }

- |                                                   |                          |
|---------------------------------------------------|--------------------------|
| 1. English Literature.                            | 9. Mathematics.          |
| 2. History.                                       | 10. Mechanics.           |
| 3. Geography.                                     | 11. Physics.             |
|                                                   | 12. Chemistry.           |

| 8. Some one other language approved by the Board. |                          |

*Provided that* (a) candidates who take Mathematics under II above must include one of the subjects 4-8; (b) candidates who take Latin under II above must include one of the subjects 9-15.

Exemption from the examination may be granted to applicants holding certificates of having passed examinations of a standard deemed by the Matriculation Board to be at least equal to the Board's examination.

#### PROFESSIONAL EXAMINATIONS.

The examinations for the M.B., Ch.B. number three. The first deals with (1) physics and chemistry, (2) biology. In each subject laboratory work is included, but the two parts can be taken separately. For neither can the candidate present himself until after matriculation and a period of approved work in the respective subjects.

*Second M.B.*—This examination may be taken in two parts: (a) anatomy and physiology, including practical work; (b) materia medica and pharmacy, including actual compounding of drugs. The candidate's certificates must show, among other things, that he has dissected during at least five terms.

*Final M.B.*—This may be divided into three parts. The first (pathology and bacteriology) may be taken at the end of the tenth term; the second (forensic medicine and public health) and the third (medicine, surgery, obstetrics, and pharmacology and therapeutics) cannot be taken before the end of the fifth year; before admission to the examination in its subjects the candidate, besides ordinary certificates, must produce proof that he has done both intern and extern maternity work, and received clinical instruction in gynaecology, in diseases of the eye, skin, or larynx, and in the administration of anaesthetics. This division covers all branches of surgery, medicine (including mental diseases and diseases of children), and obstetrics and gynaecology. First and second class honours may be obtained in this division.

The regulations and curriculum are now under revision in accordance with recent recommendations of the General Medical Council.

*M.D.*—A candidate for this degree must be a M.B., Ch.B. of the university of at least one year's standing. He presents a dissertation embodying the results of personal observation or original research, and, if this is approved, he may be required to write a short extempore essay on some topic connected with medicine, and may be examined orally on the dissertation or other work submitted.

*Ch.M.*—The candidate for this degree must have been admitted to the M.B., Ch.B. of the university not less than a year previously, and during that time must have held for at least six months a surgical appointment in a public institution affording full opportunity for the study of practical surgery. He must also have attended certain courses, including one on ophthalmology and one on bacteriology; he is then examined on the subject of surgery in all its branches.

#### FEES.

The matriculation fee is £2, and on readmission £1 10s. For each of the other examinations £6 (£7 for Ch.M.); and £3 on readmission. On conferment of the degree of Ch.M. £7 is payable, and £0 for the M.D. degree.

#### UNIVERSITY OF LIVERPOOL.

This university, besides granting degrees in medicine (M.B. and M.D.) and in surgery (Ch.B., M.Ch.Orth., and Ch.M.), gives degrees in dental surgery (B.D.S. and M.D.S.), a degree in hygiene (M.H.), and degrees in veterinary science (B.V.Sc., M.V.Sc., and D.V.Sc.). Diplomas are awarded in dental surgery (L.D.S.), tropical medicine (D.T.M.), public health (D.P.H.), veterinary hygiene (D.V.H.), and medical radiology and electrolgy (D.M.R.E.).

#### MATRICULATION.

The Matriculation Examination is governed by the Joint Matriculation Board, 315, Oxford Road, Manchester, which accepts under certain conditions the test of several other bodies as its equivalent. The Faculty of Medicine has power to exempt from examination in corresponding subjects in the first M.B. examination any student who has obtained a certificate at a Higher School Certificate examination in the group including chemistry and physics, and who has reached a standard deemed satisfactory in the subject of exemption. Of the five years' curriculum, not less than two must be passed in the university itself, one such year being subsequent to the date of passing the first M.B. Examination.

#### PROFESSIONAL EXAMINATIONS.

Candidates for the M.B., Ch.B. degrees have three examinations to pass, the first including (1) chemistry, inorganic, organic, and physical; (2) biology, including zoology and botany; (3) physics. Section 2 may be taken alone or in conjunction with Sections 1 and 3.

*Second M.B.*—This test covers (a) (1) anatomy, (2) physiology, including physiological chemistry and histology; and (b) (3) materia medica and pharmacy; (4) pharmacology. Candidates may present themselves in (a) and (b) separately.

*Final M.B.*—The subjects of the Final Examination are: (1) General pathology, morbid anatomy, and bacteriology; (2) forensic medicine, toxicology, and public health; (3) obstetrics and diseases of women; (4) surgery, systematic, clinical, operative, and practical, including ophthalmology; (5) medicine, systematic and clinical, including mental diseases and diseases of children and therapeutics. The examination is divided into three parts: Part I, subject 1; Part II, subject 2; Part III, subjects 3, 4, and 5. Candidates may present themselves for examination in the three parts at the same time, or in any two parts together, or in each part separately. Part III may not be taken until five years of study have been completed.

*M.D. and Ch.M.*—Candidates for these degrees must have received the M.B. and Ch.B. at least two years previously. Students holding equivalent degrees of other approved universities may become candidates for the M.D. degree after two years' study in the university or clinical school of the university. The M.D. candidate submits for approval a published thesis or a dissertation covering original work. The M.Ch. candidate undergoes an examination. Other information concerning the diplomas of this university and its medical school will be found on page 377.

#### FELLOWSHIPS, SCHOLARSHIPS, AND EXHIBITIONS.

The university awards Fellowships annually to students of distinguished merit, as follows:

(1) John Rankin Fellowships in Anatomy; two, each of the value of £120, tenable for two years. (2) Ethel Boyce Fellowship in Gynaecology, value £100 and tenable for one year, open to fully qualified medical students of either sex. (3) John W. Garrett International Fellowship in Bacteriology, value £100 and tenable for one year. (4) Robert Gee Fellowship in Human Anatomy, value £100 and tenable for one year. (5) Holt Fellowships in Physiology and Pathology, two in number, value £100 each and tenable for one year. (6) Johnston Colonial Fellowship in Biochemistry, value £100 and tenable for one year. (7) Thelwall Thomas Fellowship in Surgical Pathology, value £150 and tenable for one year. (8) University Fellowship, £100.

There are, in addition, scholarships and exhibitions open to medical students.

#### VICTORIA UNIVERSITY OF MANCHESTER.

This university grants the following degrees in medicine and surgery, M.B. and Ch.B. and Ch.M.; a diploma and a degree (B.Sc.) in public health; a certificate in factory and in school hygiene; a diploma in psychological medicine;

of medicine in this university. They range from £8 to £100 per annum, and are tenable in most cases for two or three years. The winter session begins on October 10th, 1923; the summer session on April 21st, 1924.

**Fees.**—An inclusive fee of 150 guineas is payable for instruction within the university, and the fee for the degrees of M.B., Ch.B. is 33 guineas. The total cost, including hospital fees, class and matriculation fees, and degree fees, is about £235.

#### EDINBURGH.

There are two Schools of Medicine: the School of the University, and the School of Medicine of the Royal Colleges of Physicians, and Surgeons of Edinburgh.

The UNIVERSITY SCHOOL.—This school, in addition to other resources of the university, has the following means of affording practical instruction: Royal Botanic Garden, Herbarium, and Museum; Zoological Laboratory and Museum of Science and Art; Physical Laboratory; Chemical Laboratory; Dissecting Room, Bone Room, and Anatomical Museum; Physiological Laboratory; Medical Jurisprudence Laboratories; John Fisher Institute of Public Health; Materia Medica Museum and Laboratory; Post-Mortem Department of the Royal Infirmary and University Pathological and Bacteriological Laboratories; Tutorial Classes of Practice of Physics, of Clinical Medicine, and Clinical Surgery, Surgery, and Midwifery; and the practice of certain other hospitals.

**Fees.**—The sessional fee for physiology, pathology, materia medica, physics, botany, public health, £5 5s. Practical anatomy, £5 5s.

pathology, and medical entomology and parasitology, £4 4s. Experimental physiology, diseases of tropical climates, practical botany, histology, operative surgery, clinical surgery (per term), experimental pharmacology, and comparative zoology, £3 3s. Practical anatomy (winter), £6 10s. 6d. Clinical medicine, £3 13s. 6d. First term, subsequent terms £3 3s. Practical chemistry, £4 14s. 6d. Regional anatomy, chemical physiology, surgical pathology, and applied anatomy, £3 11s. 6d. Tuberculosis, diseases of children, diseases of the eye, diseases of the larynx, ear, and nose, diseases of the skin, and venereal diseases, £2 12s. 6d. Advanced bacteriology, £7 17s. 6d. Clinical jurisprudence, £2 2s.

**Scholarships.**—There are many funds for the assistance of students by means of bursaries, scholarships, exhibitions, and money awards from the beginning to the end of their undergraduate career. In addition there are funds which help those who have taken a first degree in medicine and surgery to continue at work as research students. The value of these awards, and the conditions attaching to them, are so varied that those interested should consult the prospectus of the school itself. No other university is in a better, even if as good, a position to smooth the financial path of earnest students.

The School of Medicine of the Royal Colleges.—This school is composed of lecturers licensed by the Royal College of Physicians and the Royal College of Surgeons, and also recognized by the university through their *licentia docendi*; for the sake of convenience they lecture in separate buildings near to the Royal Infirmary, but form a single corporate body governed by a board consisting of five members elected by the Royal College of Physicians, five members elected by the Royal College of Surgeons, and five members elected by the lecturers in the school. This board, with the assistance of the standing committees of the school, supervises the whole management and especially the maintenance of the efficiency and discipline of the school. The different buildings at present utilized for the purposes of lecturing are the following: (1) Surgeons' Hall, Nicolson Street; (2) New School, Bristol Street; (3) Nicolson Square; (4) Marshall Street; and other places. The teaching is similar to that of the Scottish universities, and the students receive similar certificates at the close of each session. The courses on the special subjects not included in the curriculum of the Examining Boards are also conducted by teachers specially qualified in each branch, and have for the last quarter of a century formed a special feature of the school. The fees payable for class and other instruction, and including the sum payable on admission to the examination of the Conjoint Board for the triple qualification, amount to about £180. The Calendar, giving full information regarding classes and fees, can be obtained (price 6d.) on application to the Dean of the School, 11, Bristol Place, Edinburgh.

Women Students in Edinburgh.—Until the close of the summer session of 1916 women students intending to proceed to graduation in the University of Edinburgh, as well as those entering for the triple qualification of the Royal Colleges of Edinburgh and Glasgow, received their training in the Edinburgh School of Medicine for Women. Now women obtain either the university degree or the diploma of the Royal College. In the university systematic lectures are given to them by the professors in the ordinary classes, which are therefore mixed. With few exceptions, prizes, scholarships, bursaries, and similar distinctions are open to women under the same conditions as for men. The women students also have the same privileges as in the past have been given to the men of attending a certain proportion of the extramural classes taught by the lecturers of the School of Medicine of the Royal Colleges. Most of the Students' Societies are open to women, with the exception of the University Union and the Women Students' Union, and the Women's Medical Society. There is also a Women's Athletic Club, with playing fields gifted to it by the University. Information on matters connected with women's studies may be obtained from the Lady Warden, University New Buildings, Edinburgh.

#### GLASGOW.

The UNIVERSITY SCHOOL, FOR MEN.—The whole course of study required for graduation (M.B., Ch.B.) at the University of Glasgow can be taken here. Besides ample provision for lectures there is practical and clinical work at the hospital, and practical courses are conducted in the laboratories of the following departments: Surgery, Pathology, Public Health, Pharmacology, Anatomy, Chemistry, Zoology, and Botany; the Botanic Garden and the Hunterian Museum (Zoology and Pathology) are also open to students. New buildings and equipments have been provided for botany, for practical anatomy, for operative surgery, as well as for pathology; the very large additions made a number of years ago to the Chemical Laboratory rendered it one of the most extensive in Scotland. The classrooms and laboratories for the departments of Physics, Physiology, Pharmacology, Materia Medica, Medical Jurisprudence and Public Health, and Zoology are also of recent erection, and are elaborately equipped. Four additional chairs of Medicine, Surgery, Obstetrics, and Pathology have been recently established. The Professors being specially attached to the Royal Infirmary; and a number of University Lectureships in Clinical Medicine, Clinical Surgery, Venereal Diseases, Laryngology, Dermatology, Otolaryngology, Psychological Medicine, Tuberculosis, and Electrical Diagnosis and Treatment have been founded there. Four other chairs have been founded at the University, in Bacteriology, Organic Chemistry, Physiological Chemistry, Diseases of Children, and on Electrical Diagnosis and Therapeutics. The university, in short, has made great and successful efforts to extend and improve the accommodation of the medical departments, to strengthen the teaching staff, and to encourage post-graduate and research work. Three very extensive general hospitals in the city afford exceptional opportunities for clinical instruction—namely, the Western Infirmary (600 beds), near the university, to which the Registrar is attached; the Royal Infirmary (630 beds); Professors are attached; the Royal Infirmary (260 beds); and the Victoria Infirmary (260 beds); while the Royal Asylum (460 beds), the Royal Hospital for Sick Children (200 beds), the Royal Maternity and Women's Hospital (108 beds), the Glasgow Eye Infirmary (100 beds), the Ophthalmic Institution (35 beds), the fever hospitals at Belvidere (650 beds) and Ruthill (540 beds), and other institutions afford facilities for the practical study of special branches. The large general hospitals of the Parish Council are now also available for clinical instruction in Medicine and Surgery. Information regarding post-graduate study will be found at page 355.

**Bursaries.**—Bursaries continued to the Medical Faculty amount to annual values to about £1,000, while bursaries in any faculty, amounting to about the same annual sum, may be held by students of medicine, a number of both sets being open to women. Several valuable scholarships may be held by medical students who have graduated in Arts.

## WELSH NATIONAL SCHOOL OF MEDICINE.

Students can complete the whole of their curriculum in the Welsh National School of Medicine, which is an integral part of the University College of South Wales and Monmouthshire, and qualify for the degrees of M.B., Ch.B. in the university.

Further information may be obtained from the Registrar, the University Registry, Cathays Park, Cardiff.

## English Medical Corporations.

THERE are three medical corporations in England—the Royal College of Physicians of London, the Royal College of Surgeons of England, and the Society of Apothecaries of London. The first two combine for certain purposes to form what is known as the "Conjoint Board." Details concerning this body, its component Colleges, and the third licensing body here follow.

## THE CONJOINT BOARD.

This body—the Examining Board in England—deals with the qualifications of all candidates for the Licence of the Royal College of Physicians of London and for the Membership of the Royal College of Surgeons of England. It prescribes for them certain periods of study, and recommends those who satisfy it for the Licence and for the diploma of Membership respectively. The successful candidate is then entitled to register as L.R.C.P.Lond., M.R.C.S.Eng. It performs the same task in connexion with diplomas in State medicine, tropical diseases, ophthalmic medicine and surgery, and psychological medicine, jointly issued by the two Colleges in question. Under the new regulations, which apply to all students who have not passed the required preliminary tests of general education before January 1st, 1923, every candidate for the M.R.C.S. and L.R.C.P. must (1) complete five years of professional study after passing a recognized preliminary examination and a recognized pre-medical examination in chemistry and physics; (2) comply with the regulations, which may be had from the Secretary, Examination Hall, 8-11, Queen Square, Bloomsbury, London, W.C.1; and (3) pass the two professional examinations of which particulars appear below. The old regulations for the Conjoint diploma, of which an account was given in last year's *Educational Number*, still apply to students who passed their preliminary examination in general education before January 1st, 1923.

## NEW REGULATIONS FOR THE CONJOINT DIPLOMA.

The following is an outline of the regulations applicable to candidates for the L.R.C.P.Lond. and M.R.C.S.Eng., who passed the required Preliminary Examination in general education on or after January 1st, 1923. The full regulations and synopses and forms of certificate may be obtained from the secretary.

## PRE-MEDICAL EXAMINATION.

Students are required to pass a Pre-Medical examination in Chemistry and Physics conducted by the Conjoint Examining Board before commencing the five years' curriculum of professional study or some other examination recognized by the Board—namely, the examination in Chemistry and Physics for the degree in Medicine of any university recognized by the Board, the Higher School Certificates of Oxford and Cambridge Universities and the Oxford and Cambridge Schools Examination Board, the Higher Certificates of London, Bristol, Durham Universities, and the Joint Matriculation Board of the Northern Universities.

A candidate must enter for Chemistry and Physics together and he will not be allowed to pass in one without obtaining at the same time at least half the number of marks required to pass in the other subject. He will be admitted to the examination on producing evidence of having passed the required Preliminary Examination in General Education and of having received instruction during 180 hours in Chemistry and 120 hours in Physics to the satisfaction of his teachers. These courses may be commenced or attended before the required Preliminary Examination in General Education is passed.

The examination is partly written, partly oral, and partly practical. A candidate rejected in one or both subjects of the examination will not be admitted to re-examination until after the lapse of a period of not less than three months and he must produce evidence of further instruction in the subject or subjects of failure.

## PROFESSIONAL EXAMINATIONS.

There are two Professional Examinations called the First and Final Examinations. The courses of study for these examinations must not be commenced until the Pre-Medical Examination in Chemistry and Physics or some equivalent examination has been passed.

*First Professional Examination.*—The subjects of this are: Section I, (a) Anatomy, including Histology and Embryology; (b) Physiology, including Biochemistry. Section II, Pharmacology, Practical Pharmacy and Materia Medica. A candidate must have attended at a recognized Medical School courses of instruction in Anatomy, including Embryology, during five terms, during which he must have dissected the whole body, courses of instruction in Physiology, including General Biology, Biochemistry, and Biophysics, during five terms, courses of instruction in Pharmacology, Practical Pharmacy, and Materia Medica. A candidate may present himself for the two Sections together or separately, but he must take parts (a) and (b) of Section I together until he has passed in one or both parts, but a candidate will not be allowed to pass in one part unless he obtains at the same time at least half the number of marks required to pass in the other part. Section II of the examination may be passed at any time before the candidate enters for the Final Professional Examination. A candidate who produces satisfactory evidence of having passed an examination in the subjects of Section I or of either part of Section I and of Section II in the examination for the degree in Medicine conducted at a university recognized by the Board will be exempted from further examination in such subject or subjects.

*Final Professional Examination.*—The subjects of this are: Section I, (a) Pathology, including Morbid Anatomy, Morbid Histology, and Clinical Pathology; (b) Bacteriology. Section II, Part I, Medicine, including Medical Anatomy, Forensic Medicine, and Public Health; Part II, Surgery, including Surgical Anatomy and the use of Surgical Appliances; Part III, Midwifery and Gynaecology. The examination is partly written, partly practical, partly clinical, and partly oral. A candidate may take Sections I and II and the three parts of Section II of the Final Examination separately or may take the whole examination together. He will be required to produce the certificates required by the regulations before being admitted to the respective parts of the examination. A candidate who produces evidence of having passed an examination for a degree in Medicine in the subjects of Pathology and Bacteriology at a university recognized by the Board is exempted from Section I.

## FEES.

The fee for the Pre-Medical Examination is three guineas, for re-examination in Chemistry two guineas, and for re-examination in Physics one guinea. The fee for the First Professional Examination is ten guineas, for re-examination after rejection in Section I six guineas, for re-examination after rejection in either part of Section I three guineas, for re-examination after rejection in Section II three guineas. The fee for admission to Section I of the Final Professional Examination is four guineas, for admission to Section II, Part I, ten guineas, Part II ten guineas, Part III six guineas; and the re-examination fees are respectively three guineas, six guineas, and four guineas.

## ROYAL COLLEGE OF PHYSICIANS OF LONDON.

This College has three grades—its Licentiates, its Members, and its Fellows. The Licence is now only issued through the Conjoint Board. The Membership is only granted to those who have passed the final examinations for the Licence, or those who are registered practitioners and graduates of a recognized university; in any case they must be persons over 25 years of age. Candidates are examined in pathology and the practice of physic, partly in writing and partly viva voce; they are also examined in Latin, and either Greek, French, or German. The fee for the Membership is £42, or in the case of a Licentiate, £21. There is a fee of £6 6s., payable before entrance to the examination, which in the case of successful candidates is reckoned as part of the Membership fee. The body of Fellows is maintained by election from among the Members.

## ROYAL COLLEGE OF SURGEONS OF ENGLAND.

This College has two grades—Members and Fellows. The Members are admitted as stated in the section dealing with the Conjoint Board. The Fellowship is granted after examination to persons at least 25 years of age who have been engaged in professional studies for six years. There are two examinations for the Fellowship—the first in anatomy and physiology, which may be passed after the third winter session; the second, chiefly directed to surgery, which may

There are numerous well arranged hospitals in and around the city, and almost all of these are recognized for teaching purposes by the National University of Ireland, and by like bodies elsewhere in the British Isles. Among them are the Mater Misericordiae Hospital, with 345 beds; Dr. Stevens's Hospital at Kingsbridge, with 150; Meath Hospital and County Dublin Infirmary, with 160; Mercer's Hospital, close to Trinity College, with 120; the Royal City of Dublin Hospital, with 124; the Adelaide Hospital, with 140; the Royal Victoria Eye and Ear Hospital, with 100 beds; Sir Patrick Dun's, which has a direct connexion with the School of Physics, and the combined institutions formed by the Hardwicke Fever Hospital, the Richmond Surgical Hospital, and the Whitworth Medical Hospital, with an aggregate of 230 beds. As for the famous Dublin medical institution known as the Rotunda Hospital, this practically consists of two distinct hospitals, and is believed to be the largest combined maternity and gynaecological hospital in the British Isles. It receives nearly 3,000 patients every year, and, apart from ordinary out-patient work of a gynaecological order, annually attends some 2,000 women at their own homes during their confinement. It possesses residential quarters for students, and, taken as a whole, offers exceptional opportunities for study both to ordinary students and to medical graduates of any nationality.

#### Clinical Work.

#### BREAST.

The Medical School is part of the Faculty of Medicine of Queen's University, Belfast, and provides a complete medical curriculum for all purposes. The laboratories in connexion with the departments of biology, chemistry, physics, pathology, anatomy, physics, and materia medica are all excellent, and there is a Students' Union which gives students the advantages of dining rooms, reading rooms, a library, and various recreation rooms. Women are eligible as students. Clinical instruction is given at the Royal Victoria Hospital. It was rebuilt a few years ago and has 300 beds, and the Mater Infirmerum Hospital, which has 150 beds. Other hospitals open to the students of the university are: the Mater Infirmerum Hospital, the Clatter Hospital for Women and Children, the Hospital for Sick Children, the Ophthalmic Hospital; the Bannister Eye, Ear and Throat Hospital; the Union Infirmary and Fever Hospital; the Fever Hospital, Purdy'sburn; the District Lunatic Asylum, the Samaritan Hospital, Forster Green Hospital for Diseases of the Chest, and the Belfast Hospital for Skin Diseases.

**Scholarships.**—(1) Twelve of the value of £40 each, are assigned as Entrance Scholarships in the Faculties of Arts, Science, and Medicine, tenable for one year; (2) sixteen Professional Scholarships, tenable for one year from £15 to £40 each; (3) one Hutchinson Stewart Scholarship, value from £15 to £40 each; (4) one MacLay Wilson Scholarship, £12, in mental diseases; (5) awarded triennially; (6) Isabella Tod Memorial Scholarship, £100, awarded triennially; (7) awarded annually, value about £112; (8) two MacLay Scholarships of £300 in Physiology and Pathology; (9) numerous seasonal prizes. There is also a post-graduate research fund, open to all graduates of not more than three years' standing. Gold medals are awarded at the M.D. examination.

**Fees.**—The cost of the curriculum intended for students proceeding to the degrees of the Queen's University of Belfast is, approximately, £150. This includes examination fees and a percentage for attendance at the Royal Victoria Hospital or the Mater Infirmerum Hospital, and fees for the special hospitals. The course for the Conjoint Board costs about the same amount.

The Regulations of the Medical Faculty, containing full information, can be obtained on application to the Secretary, Queen's University, Belfast, price 4d.

This institution, formerly known as Queen's College, Cork, is one of the constituent colleges of the National University. It holds examinations for all the faculties of that university. In addition to continuing the work which it has hitherto performed—namely, that of providing education adapted to the needs of medical students at all stages of their career. Its first aim is to fit students for the degree of the Secretary and Bursar, University College, Dublin.

#### ST. ANDREW AND DUNDEE.

The medical departments in these two teaching centres cater specially for students proceeding to the degrees of the University of St. Andrews, but admit other students as well. In the former city the United College provides education in all subjects of the first two years. In Dundee, University College provides for the needs of students from the beginning to the end of the five years' curriculum. Its buildings are modern, and contain fully equipped laboratories. The work of the school is facilitated by various institutions. The class fees are from £6 6s. to £5 12s. 6d. for systematic classes, and from £4 14s. 6d. to £4 4s. for practical classes. The hospital ticket is £1 8s. for three months, £4 4s. a year, or perpetual £13 6s. 8d. in one sum. The inclusive or composition fee for the curriculum is £182. In connexion with both institutions there are bursaries and scholarships of considerable value, which are awarded after competitive examination. Information as to these can be obtained from the Secretary of the University of St. Andrews. Information regarding the clinical facilities may be obtained from the Dean of the Medical Faculty, Medical School, Dundee.

#### Clinical Work.

Good opportunities for clinical work are afforded by the Dundee Royal Infirmary, the instruction given thereat being recognized for purposes of graduation by all the Scottish Universities, the University of London, the University of Cambridge, the National University of Ireland, and by the Royal Colleges of England and Scotland.

There is a choice of six schools for those pursuing their medical studies in Ireland. For clinical instruction the choice is equally satisfactory and varied, though the hospitals themselves are comparatively small. Some account of the schools follows.

#### School of Physics.

#### DUBLIN.

This school is in Trinity College, Dublin, and is carried on under the joint auspices of the University of Dublin and the Royal College of Physicians in Ireland, the Kings' professors of medicine (physiology), practice of medicine, materia medica, and midwifery being appointed by the latter. Clinical instruction is given at Sir Patrick Dun's Hospital, and some twelve other metropolitan hospitals and asylums are recognized by the Board of Trinity College. The courses of instruction are open to all medical students whether they belong to the university or not.

**The Schools of Surgery.**

These are schools carried on in Dublin under the supervision and control of the Council of the Royal College of Surgeons. They are formed of the College's own school, combined with two famous old medical schools—Carmichael and Ledwith; they are attached to the College by charter. The buildings contain spacious dissecting rooms, special pathological, bacteriological, public health, chemical, and pharmaceutical laboratories. Advantage can be taken of the lectures and instruction afforded by students otherwise unconnected with the College.

**Prizes.**—Among the prizes annually awarded are: The Barker Anatomical Prize (£26 3s.); the Gold Medal in Surgery, the Stony Mayne Scholarship (£8); the Gold Medal in Anatomy; the Memorial Gold Medal in Anatomy; the H. Macanaghion Jones Gold Medal for Midwifery and Gynaecology; class prizes, accompanied by silver medals, will also be given in each subject.

A prospectus can be obtained post free on application to the Registrar, Royal College of Surgeons, Dublin.

University College, Dublin.

This is one of the constituent colleges of the National University of Ireland, and at present conducts its work at buildings on St. Stephen's Green. It possesses a good library, and the arrangements for the teaching of medical students from beginning to end of the curriculum are adequate. Applications for other information may be addressed to the Secretary and Bursar, University College, Dublin.

## FEES.

It is estimated that the class, examination, and other fees for the M.B., Ch.B. come altogether to about £217, the separate examination fees included in this calculation being as follows:

|                          | £  | s. | d. |
|--------------------------|----|----|----|
| First Professional.. ..  | 9  | 9  | 0  |
| Second Professional.. .. | 7  | 7  | 0  |
| Third Professional.. ..  | 6  | 6  | 0  |
| Final.. ..               | 11 | 11 | 0  |

Re-entry in any subject in which the candidate has failed entails a fresh payment of £1 1s. Candidates for the M.B. and Ch.M. pay £21, and on re-entry £5 5s.

More detailed information with regard to the University of Edinburgh can be obtained from the *Medical Programme*, price 6d., which is published by Mr. Thin, 55, South Bridge, Edinburgh, or on application to the Dean of the Faculty of Medicine. Similar information about Glasgow should be sought from the Assistant Clerk, Matriculation Office, Glasgow. With regard to Aberdeen, application may be made to the Secretary of the Medical Faculty, Marischal College. In respect of St. Andrews information can be obtained either from the Secretary of the University, or, alternatively, the Secretary of the United College, St. Andrews, or the Secretary of University College, Dundee, these being the two constituent colleges of the University of St. Andrews.

Finally, it should be mentioned that in connexion with all the Scottish universities there are valuable bursaries and scholarships, some information as to which will be found in the article on Medical Schools.

## The Scottish Corporations.

THERE are three medical corporations in Scotland—the Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Royal Faculty of Physicians and Surgeons of Glasgow. Their licences can be separately obtained only by persons who are already in possession of a recognized qualification—in surgery in the case of the College of Physicians, and in medicine in the case of the College of Surgeons and the Faculty of Physicians and Surgeons of Glasgow. All others must submit to the examinations held by the Conjoint Board which the three corporations have combined to form. Details concerning this Board and its component colleges follow. The conditions on which their higher qualifications are granted will be found set forth separately in connexion with each corporation.

### THE CONJOINT BOARD IN SCOTLAND.

This body has charge of all questions connected with candidates for the Conjoint Licences of the Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Royal Faculty of Physicians and Surgeons of Glasgow. Those finally approved by it are entitled to registration and to the initials denoting the Licences of the three bodies concerned—namely, L.R.C.P. Edin., L.R.C.S. Edin., and L.R.F.P.S. Glasg. The Board requires all candidates to comply with the regulations of the General Medical Council. It has an arts examination of its own, but is prepared to accept in its place any of the other educational tests approved by the General Medical Council. All candidates must obtain registration with the General Medical Council.

#### *Professional Curriculum for Candidates registered as Medical Students prior to January 1st, 1923.*

Subsequent to registration as a medical student the candidate must pass not less than five years in medical study, each comprising a winter and a summer session. The Board does not insist that candidates shall pursue their study at any particular place, and is prepared to accept certificates of having attended the necessary courses from any recognized medical school.

Its examinations are four in number, each of them being held four times every year, and these will fall to be held twice in Edinburgh and twice in Glasgow during the next period; it is open to candidates to present themselves for

examination at either place. The first examination deals with physics, chemistry, and elementary biology; the second with anatomy and physiology, including histology; the third with pathology and materia medica, including pharmacy; and the final with (1) medicine, including therapeutics, medical anatomy, and clinical medicine; (2) surgery, including surgical anatomy, clinical surgery, and diseases and injuries of the eyes; (3) midwifery and diseases of women and of newborn children; and, if it has not been passed previously, (4) medical jurisprudence and hygiene. Candidates may also be examined on diseases of children, diseases of the ear and throat, insanity, vaccination, etc.

These examinations must be passed in due order, and before admission to any of them the candidate must supply certificates showing that he has completed the due periods of study of their subjects. He can present himself in any single subject of the first three examinations. As regards the final examination, a candidate can present himself in medical jurisprudence and hygiene at any time after completion of the third examination and of his study of these subjects; but in medicine, surgery, and midwifery he cannot present himself until the completion of five years' study, and he must take them all simultaneously. A candidate who takes up several subjects of an examination or the whole of the subjects at one time, but fails in some of them, is credited at the next examination with those subjects in which he has been approved.

Part or entire exemption from the first three examinations may be granted to those who have already passed before other bodies examinations deemed by the Board equivalent to its own; but all candidates for the Conjoint licence must sit for the final examination, and at no examination can a candidate present himself within three months of his rejection by some other licensing body.

#### *Professional Curriculum for Candidates registered as Medical Students after January 1st, 1923.*

The curriculum has been extended to meet the recommendations of the General Medical Council. Candidates when applying for copies of regulations should state date of medical registration.

## FEES.

It is estimated that the total cost of lectures and fees for the conjoint licence is about £152. The separate examination fees are as follows: First, Second, and Third Professional, £5 each; Final £15. On re-entry for any of the first three examinations £3, and on re-entry for the Final, £5. If the re-entry is only in one or two subjects the fees are smaller.

Information concerning this Board should be sought either from Mr. D. L. Eadie, 49, Lauriston Place, Edinburgh, or from Mr. Walter Hurst, Faculty Hall, 242, St. Vincent Street, Glasgow.

### ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.

This College has three grades—Licentiate, Membership, and Fellowship—all of which are open to men and women. The regulations applying to candidates for the Licentiate have already been generally indicated. If desirous of receiving it apart from those of the other two corporations they must be holders of a surgical qualification recognized by the College, and must pass an examination corresponding to the medical part of the Final Examination of the Conjoint Board, and conditioned in the same way, and also an examination in materia medica. The fee for examination is 15 guineas, a special examination being obtainable on due cause being shown, and on payment of 5 guineas extra. Ordinary examinations take place monthly on the first Wednesday, except in September and October. Candidates for the Membership must be either Licentiates of a British or Irish College of Physicians, or alternatively graduates of medicine of a university approved by the Council, and in either case not less than 24 years of age. Candidates are examined in medicine and therapeutics, and in one further subject at choice. This may be either (a) one of the departments of medicine specially professed; (b) psychology; (c) general medicine specially professed; (d) medical jurisprudence; (e) pathology and morbid anatomy; (f) medical jurisprudence; (g) public health; (h) midwifery; (i) gynaecology; (j) diseases of children; or (k) tropical medicine. The fee to be

Hospital near Charing Cross, the Royal Eye Hospital, Southwark, and the Central London Ophthalmic Hospital, Judd Street, W.C.1.

**Feet Hospitals.**—The Metropolitan Asylums Board has under its control a good many institutions in and around London for the treatment of the more serious zymotic disorders; it makes special arrangements for the instruction of students in this subject, and grants certificates at the end of the courses. Detailed information should be sought from the Clerk to the Board, Victoria Embankment, E.C.4.

**Chest Hospitals.**—The largest of these is the Brompton Hospital for Consumption, which has 333 beds and a large sanatorium at Friemly with 150 beds. There is also the City of London Hospital for Diseases of the Chest, Victoria Park, with 175 beds, and the Royal Hospital for Diseases of the Chest, City Road, which has recently amalgamated with the Royal Northern Hospital, Holloway Road.

**Nose, Throat and Ear Hospitals.**—The institutions which confine their work to disorders of the throat, nose and ear all make special arrangements for the benefit of senior and post-graduate students. They are the Metropolitan Ear, Nose and Throat Hospital, Fitzroy Square; the Royal Ear Hospital, Dean Street; the Central London Hospital for Diseases of the Ear, Nose and Throat, Gray's Inn Road; and the Hospital for Diseases of the Throat, Golden Square—the latter, which possesses 75 beds, being the largest of the four institutions.

**Miscellaneous Special Hospitals.**—Among these are the Bethlehem Royal Hospital, St. George's Fields, S.E.1, which confines its work to the treatment of mental diseases, and includes a department for nervous and early mental disorders; St. Peter's Hospital for Stone and Urinary Diseases, Henrietta Street, Covent Garden; St. Mark's Hospital, City Road, which devotes itself to the treatment of diseases of the rectum, including cancer and fistula; the National Hospital for Diseases of the Heart in Westminster Lane, W.1; St. John's Hospital for Diseases of the Skin, in Leicester Square; the Hospital for Diseases of the Skin, Stamford Street, Blackfriars; and the National Hospital for the Paralytic, Epileptic, Queen Square.

Detailed information as to the teaching arrangements of all these institutions may be obtained on application to their secretaries.

## WOMEN IN MEDICINE.

Women are admitted to all the medical examinations of the following qualifying bodies: all the Universities of Great Britain and Ireland, with the exception of Cambridge; the Royal College of Physicians of London and the Royal College of Surgeons of England; the Society of Apothecaries of London; the Conjoint Boards of Scotland and of Ireland. The regulations of the various universities and colleges and those of the General Medical Council set out in previous sections apply to women in the same way as to men.

**Medical Education of Women.**  
The school which admits women only is the London (Royal Free Hospital) School of Medicine for Women, which is one of the constituent schools of the Medical Faculty of the University of London. Glasgow University (see p. 379) has Queen Margaret College for the use of students of the University of London. The medical schools of the College Hospital Medical School, the medical schools of the English, Scottish, and Irish Universities and Colleges are open to women. The arrangements for women students in Edinburgh are briefly indicated on page 379; women enrolled in this university are, however, not guaranteed a course in Practical Obstetrics in the Maternity Hospital. Women can also attend the medical school attached to University College, Cardiff. As regards the London School of Medicine for Women, particulars will be found at page 374 in the article on London Medical Schools.

Women hold many appointments as residents in general hospitals, in hospitals for women and children, and in a large number of sanatoriums, infirmaries, fever hospitals, and asylums. Many medical women are also engaged in public health work.

health, tuberculosis, and school inspection work, as well as at infant welfare centres and venereal disease clinics; they can also become prison medical officers and inspectors of the mentally deficient. A considerable number of medical women are engaged in private practice, both as consultants or specialists and as general practitioners.

In view of the very great increase during the past eight years in the number of women medical students it may, perhaps, be well to direct the attention of those who contemplate entering the profession to the note of caution which has been sounded from time to time in these columns. It is desirable that women who propose to study medicine should reflect carefully on the keen competition for posts which has existed since the war, and when qualified, consider practice and specialization, more especially in obstetrics and gynaecology. There is a large field opening in India, both in practice and in the women's services of that country. Applications for particulars regarding the women's medical service for India may be addressed to the Hon. Secretary, United Kingdom Branch of the Comptess of Dufferin's Fund, c/o Sir Havelock Charles, G.C.V.O., India Office, Whitehall, S.W.1.

The British Medical Association was the first of all professional organizations to lay down the principle that no distinction should be made on the ground of sex as regards the emoluments to women members of the profession. Attempts are continually being made by public authorities to obtain the services of women doctors at lower salaries than those paid to men, and the Association looks to all medical women to help it in resisting such attacks upon the solidarity of the profession. In its constant efforts to maintain this principle the Association works in close co-operation with the Federation of Medical Women. In defence of the principle the Association has at various times fought—usually with success—Government departments and local authorities to recognize the justice of the claim that equal pay should be given for equal work by the machinery, local and central, of the Association has been put into operation, and as a result the authority has generally been seen fit to drop the proposed distinction between men and women practitioners or give up the attempt to fill the post.

## DEGREES FOR PRACTITIONERS.

At one time it was almost the universal custom for medical students educated in London and aiming at general practice to seek a university degree, and as that custom still prevails to a considerable extent a large proportion of medical men in England possess diplomas or licences to practice but not degrees in medicine. This is a fact which they sometimes and reason to regret, and to such practitioners the following paragraphs may be of interest. It should be noted, however, that the M.D. Brussels diploma, if obtained subsequently to June, 1886, is not registrable, and that the University of Brussels no longer holds special examinations for foreign medical practitioners.

**UNIVERSITY OF LONDON.**  
Registered medical practitioners who have passed the First Examination for medical degrees and the Second Examination for medical degrees, Part I, may proceed to the Second Examination for medical degrees, Part II, and M.B., B.S. Examinations for medical degrees. The medical schools of the University of London, the medical schools of the College Hospital Medical School, the medical schools of the English, Scottish, and Irish Universities and Colleges are open to women. The arrangements for women students in Edinburgh are briefly indicated on page 379; women enrolled in this university are, however, not guaranteed a course in Practical Obstetrics in the Maternity Hospital. Women can also attend the medical school attached to University College, Cardiff. As regards the London School of Medicine for Women, particulars will be found at page 374 in the article on London Medical Schools.

## QUEEN'S UNIVERSITY, BELFAST.

The degrees granted by the Medical Faculty of this university are as follows: Bachelor of Medicine (M.B.), Bachelor of Surgery (B.Ch.), Bachelor of Obstetrics (B.A.O.), Doctor of Medicine (M.D.), Master of Surgery (M.Ch.), Master of Obstetrics (M.A.O.). The university also confers a diploma in public health. The first three degrees mentioned serve as a qualification for admission to the *Medical Register*, and are not granted separately. In addition to matriculating and passing his professional examinations, a candidate for these degrees must have passed three of the regulation five years as a student at the Belfast School of Medicine. Degrees in dental surgery (B.D.S. and M.D.S.) are conferred by the university and also a diploma in dental surgery (L.D.S.).

## PROFESSIONAL EXAMINATIONS.

The examinations for the M.B., B.Ch., B.A.O. are four in number. The first deals with: (1) Inorganic, organic, and practical chemistry, (2) experimental and practical physics, (3) botany and practical botany, (4) zoology and practical zoology. It is divided into two parts, of which botany and zoology form one. The Second Examination covers anatomy and physiology, and may be taken at the end of the second year of the student's career. The Third Examination includes: (1) Pathology, (2) materia medica, pharmacology, and therapeutics, (3) medical jurisprudence, and (4) hygiene. To be valid a certificate in regard to the study of the subjects of this examination must show that the work has been done after the First Examination has been passed.

The Final Examination includes: (1) Medicine, (2) surgery, (3) midwifery, (4) ophthalmology and otology. The student may pass in all subjects at once at the end of his fifth year, or he may divide the examination into two parts—namely, (1) systematic, (2) clinical, practical, and oral. The first part may be taken at the end of the fourth year, but for the second part the candidate may not present himself until the end of his fifth year, but students invariably take both parts at the end of their course. No certificate in regard to the study of the subjects of this examination will be valid unless the work was done subsequent to passing in all the subjects of the Second Examination.

## THE HIGHER DEGREES.

Candidates for the degree of Doctor of Medicine must be graduates in medicine of at least three years' standing, unless they hold also a degree of the university in arts or science, in which case a standing of two academic years will suffice. Moreover, candidates must be able to show that the interval has been passed in the pursuit of such courses of study or practical work as may be prescribed. The degree may be conferred either (a) after a formal examination, or (b) in recognition of the merits of a thesis or of some piece of original study or research carried out by the candidate, followed by an oral or other examination in its subject. When an ordinary examination is imposed it will include (1) a written paper on the principles and practice of medicine, (2) a commentary on a selected clinical case, (3) a clinical and viva voce examination, and (4) a written paper and clinical or practical and viva voce examination on a subject chosen from the following list: (a) Human anatomy, including embryology, (b) physiology, (c) pathology, (d) pharmacology and therapeutics, (e) sanitary science and public health, (f) forensic medicine and toxicology, (g) mental diseases. The regulations for the degrees of M.Ch. and M.A.O. are of the same general nature.

## NATIONAL UNIVERSITY OF IRELAND.

The National University of Ireland carries on most of its educational work through three constituent colleges—one in Dublin, one in Cork, and one in Galway. Each of these provides a full medical curriculum, and all candidates for the medical degrees of the university must pass three of their five years of study at one or other of them. These years do not count except after matriculation or recognition as a student of the Medical Faculty obtained in some other fashion. The candidates at each constituent college are examined thereat by the university, and a common standard of educa-

tion is secured by all courses of instruction and the regulations concerning them having to be approved by the Senate, after considering report thereon from the Board of Studies of the university. In addition to the ordinary degrees in medicine and surgery, the university grants those of Bachelor and Master of Obstetrics, Bachelor and Doctor of Science in Public Health, and Bachelor and Master in Dental Surgery, as well as diplomas in Public Health, in Mental Diseases, and in Tropical Medicine.

Application for other information may be made to the Registrar, National University of Ireland, Dublin.

## The Irish Corporations.

THERE are three licensing bodies other than the Medical Faculties of the Universities, and in Dublin, just as in London, there is a Royal College of Physicians of Ireland, a Royal College of Surgeons in Ireland, and an Apothecaries' Hall. In Ireland, as in England, the two Colleges have formed an examining Conjoint Board, which is responsible for the recommendation of candidates to the two bodies for their respective licences. The Apothecaries' Hall of Ireland, like the Apothecaries' Society of London, gives its licence separately.

## THE CONJOINT BOARD IN IRELAND.

This body requires of candidates the passage either of its own preliminary examination in the subjects of general education or proof that the candidate has passed one of the tests accepted by the General Medical Council.

## PROFESSIONAL EXAMINATIONS.

There are four professional examinations, the first of which cannot be passed earlier than the end of the first winter session, nor the fourth before the conclusion of full five years of medical study. Before being admitted to any of them the candidate must show that he has studied the different subjects in practice and theory for the requisite periods, certificates to this effect being accepted from the authorities of most of the recognized medical schools at home and abroad. The first and second examinations deal respectively with (a) chemistry and physics, and (b) biology; and (a) anatomy, and (b) physiology and histology. All parts of these examinations, as also of the following one, which deals with (a) pathology, (b) materia medica, pharmacy, and therapeutics, (c) public health and forensic medicine, may be taken separately.

*Final Examination.*—This is divided into three divisions, which cannot be completed until at least four years have passed in medical studies other than those for the first examination, and five years at least since the beginning of the curriculum. The divisions are (a) medicine, including fevers, mental diseases, and diseases of children; (b) surgery, including ophthalmic and operative surgery; (c) midwifery, including diseases of women and newborn children, and the theory and practice of vaccination. Candidates are recommended to present themselves in all the subjects of the Final Examination at one time, but a candidate at or after the end of the fourth year may present himself in any one of the divisions (a), (b), or (c), provided he has completed his curriculum as far as concerns the division in which he presents himself.

*Fees.*—Preliminary Examination, £2 2s.; re-examination, £1 1s. First Professional Examination, £15 15s.; Second, £10 10s.; Third, £9 9s.; Final, £6 6s.; re-examination fee is £2 2s. for each division.

Further information can be obtained from Mr. Alfred Miller, Secretary of the Committee of Management, Royal College of Surgeons, 123, St. Stephen's Green, Dublin.

## ROYAL COLLEGE OF PHYSICIANS OF IRELAND.

Those whose names already appear on the *Medical Register* can obtain the separate Licence in Medicine of this College, and its Licence in Midwifery. In either case an examination has to be passed in the subjects indicated, questions on midwifery, hygiene, and jurisprudence being included in the examination for the Licence in Medicine. For the Licence

to August 10th; (b) a Course on Diseases of Children from July 30th to August 10th; (c) a General Medical Course; (d) a General Surgical Course. Courses (c) and (d) extend for four weeks from August 13th to September 8th. Similar courses are held each year.

The Course in Obstetrics and Gynaecology comprises instruction in Clinical Midwifery and Clinical Gynaecology, and Ante-Natal Clinics, etc.

Surgical Clinics and Special Clinics on Diseases of the Skin, Venereal Diseases, Child Welfare, Mental Defect, Ear and Throat, Dental Clinics, and Ante-Natal Clinics. The General Medical Course includes Lecture Demonstrations, and where possible, practical instruction on Medical Anatomy, Medical Side-room Work, Examination of the Blood, X-Ray and Electro-therapeutic, and Post Mortem; Clinical Instruction in Medicine, Diseases of Children, Diseases of the Skin, and Infectious Diseases; and Special Instruction in the Diseases and Methods of Examination of the Nervous, Circulatory, Respiratory, Alimentary, and Renal Systems, and in Diseases of the Duodenum, Gall-bladder, and Pancreas. The General Surgical Course includes Lecture Demonstrations on Surgical Anatomy, Surgical Pathology, and Surgical X-Ray Diagnosis; Clinical Instruction in Surgery at the Royal Infirmary and Royal Hospital for Sick Children; Clinical Instruction in Venereal Diseases; Surgical Out-patients; Surgical and Gynaecological Operations and Special Instruction in Abdominal and Genito-Urinary and other branches of Surgery.

A series of Special Lectures, open to all graduates, is being delivered twice weekly during the month, on subjects of general medical and surgical interest, including recent advances in treatment. The following special courses have also been arranged: Examination of the Blood, Vaccine Therapy, Physiological and Biochemical Methods in Clinical Medicine, Diseases of the Ear, Nose and Throat, and Venereal Diseases.

Particulars regarding the courses, dates of commencing, fee, etc., may be had on application to the Honorary Secretary, Post-Graduate Courses in Medicine, University New Buildings, Edinburgh.

GRADUATE MEDICAL TEACHING IN GLASGOW.

Organized post-graduate medical teaching is available in Glasgow under the auspices of the Post-Graduate Medical Association. This association is composed of practically all the teaching institutions in Glasgow and the various teachers giving post-graduate instruction, and its business is managed by a board elected periodically by them. The chairman of the board is Principal Sir Donald MacLachlan, G.B.E., M.D., and the vice-chairman Sir Hector G. Cameron, G.B.E., M.D. During the winter months special courses in various subjects are conducted, and there is a series of weekly demonstrations specially designed for local practitioners. A comprehensive scheme of Clinical Courses is carried out during the summer months, from May till October, and arrangements have also been made whereby a limited number of graduates may become attached to wards or out-patient departments nominally as clinical assistants for definite periods throughout the year. As such they work under the direct supervision of the physician or surgeon in charge, and carry out such detailed investigations as directed. Those desiring further information should apply to Dr. J. N. Crickshank, Acting Secretary, Post-Graduate Medical Association, University, Glasgow.

Courses for Medical Graduates at Bristol.

The University of Bristol provides courses of post-graduate study for practitioners. Details of set courses at the Royal Infirmary and General Hospital are announced locally. In addition, practitioners may become clinical assistants in medicine, surgery, or special subjects for periods of a month or more.

The University also holds courses of demonstrations in out-lying centres in the West of England. Resident practitioners form themselves into a committee and consider the type and extent of demonstrations required. The University informs them of the results of their committee's decision.

British Medical Association. Many of these hospitals are of world-wide renown, and are attended by post-graduate students from all parts of the world. Special notes may perhaps be made of the London School of Tropical Medicine, Endsleigh Gardens, N.W.1, and the Maudsley Hospital, Denmark Hill, S.E.5.

#### FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.

Under the auspices of the Fellowship of Medicine regular "refresher" courses in general medicine and surgery, each lasting two weeks, are held once a month at the various metropolitan post-graduate hospitals. The fee for each course is 7 guineas. Courses in special subjects—ophthalmology, diseases of children, proctology, diseases of heart and nervous system, gynaecology, etc.—are given from time to time at the various special hospitals. Particulars of these courses can be obtained from the secretary. The Fellowship issues a monthly Bulletin containing a programme of the work in the various hospitals, specifying the names of teachers or lecturers, together with the time and place at which their instruction is given. This list is arranged under the headings of the various sections of the course—for example, diseases of the chest, ophthalmology, radiology, venereal diseases, etc. Announcement is also made of special courses of clinical lectures, some of which are occasionally held out of London. Special courses in general medicine and surgery, cardiology, dermatology, diseases of children, ophthalmology, proctology, and other subjects have been arranged up to June, 1921, by the Fellowship of Medicine and Post-Graduate Medical Association. The programme for this month includes a two weeks' course in general medicine and surgery, from September 10th to 22nd, at the Hampstead General Hospital, in conjunction with the Hospital for Epilepsy and Paralysis, Madia Vale, the North-Western Fever Hospital, and Paddington Green Children's Hospital. There will also be a special course of instruction in infant diseases at the Infants' Hospital, from September 3rd to 21st, a course in ophthalmology at the Central London Ophthalmic Hospital, from September 3rd to 20th, and a course in dermatology at St. John's Hospital for Diseases of the Skin, from September 17th to October 18th. Particulars of the courses may be obtained from the Secretary of the Fellowship of Medicine. (Telephone Mayfair 2296). The Secretary, Miss A. A. Willis, (The offices of the Fellowship are at 1, Windpole Street, W.1) is in attendance daily from 10 a.m. to 5 p.m., excepting Saturday. The annual subscription for membership of the Fellowship of Medicine and Post-Graduate Medical Association has been fixed at a minimum of 10s.

PROVINCIAL COURSES.

In the Provinces post-graduate courses have been organized in connection with the universities at Birmingham, Bristol, Edinburgh, Manchester, and Oxford, and through the Post-Graduate Medical Association at Glasgow. Special courses also exist at Cambridge, Durham, Leeds, and elsewhere. Liverpool has its School of Tropical Medicine. Interesting experiments in post-graduate work for practitioners in a locally or limited originally at a medical school may be recorded in the South-West London Post-Graduate Association, St. James's Hospital, Ouseley Road, Baltham, in a course at Addenbrooke's Hospital, Cambridge, during the Long Vacation, and in a lightning week-end course at St. Mary's Hospital, Paddington, for old students of the hospital.

It is a matter for satisfaction that the interest in post-graduate medical education is becoming more widespread; and in the development of this interest it is not impossible that the British Medical Association may take a part under the enlargement of the scope of its activities which its new buildings in Bloomsbury will render possible.

LIVERPOOL POST-GRADUATE COURSES.

In connection with the University and Royal Colleges, post-graduate courses have been arranged this year from July 16th to September 8th inclusive, comprising: (a) A Course in Obstetrics and Gynaecology which was held from July 16th to August 1st, 1921. British Medical Association, 129, Strand, N.W.1.

requirements of the Universities of London, Oxford, and Cambridge in general pathology and pharmacology.

**Appointments.**—All appointments are made according to the merits of the candidates, as determined by a committee of the medical staff. Sixteen out-patient officers, eight house-physicians, twenty-five assistant house-surgeons, eight house-surgeons, four ophthalmic house-surgeons, two genito-urinary house-surgeons, and nine resident obstetric assistants are appointed annually. The house-physicians and house-surgeons, obstetric residents, ophthalmic house-surgeons, and genito-urinary house-surgeons hold office for six months each, and receive free board and lodging in the college. Every student is provided with rooms and commons in the hospital during the period of his "take in" as senior dresser. In addition to the clerkships and dresserships in the medical and surgical wards, students are appointed to the posts of clinical assistant, dresser, or clerk in the special departments of ophthalmology, laryngology, gynaecology, diseases of children, diseases of the nervous system, dermatology, otology, actino-therapeutics, anaesthetics, dentistry, orthopaedics, vaccine, tuberculosis, and genito-urinary and venereal disease; clinical assistantships in the various special departments are open to post-graduates.

**Scholarships, Prizes, etc.**—The following scholarships in Arts and Science are awarded. A. Open Junior Scholarships: (1) An Arts Scholarship of the value of £100, (2) a Science Scholarship of the value of £100; these are awarded annually in July. (3) A War Memorial Scholarship of the value of £200, awarded alternately in Arts and Science. This Scholarship is open every other year; the next award will be made in July, 1924. B. Confined Scholarship in Science. A Junior Science Scholarship of the value of £100 is offered for competition, annually in September, to candidates who have attended preliminary science classes at this school. Candidates for these scholarships (male students only) must be under 21 years of age on October 1st of the year of the competition. C. Open Senior Science Scholarships: (1) A War Memorial Scholarship of the value of £80, (2) an Open Scholarship of the value of £80; both of these are awarded annually in July. Full particulars as to the scholarships may be obtained from the Dean of the Medical School. Junior prizes for general proficiency, £20, £15, £10; Hilton prize for Dissection, £5; Michael Harris prize for Anatomy, £10; Sands-Cox Scholarship for Physiology, £15 for three years; Wooldridge Memorial prize for Physiology, £10; Beaney prize for Pathology, £34; Treasurer's gold medal in Medicine, Treasurer's gold medal in Surgery, and the Golding-Bird gold medal and scholarship for Bacteriology and the £200, are awarded annually after competitive examination. The Gull Studentship in Pathology of the value of £250 per annum, the Beaney Scholarship in Materia Medica, of the annual value of about £50, and the Anderson Demonstratorship in Clinical Chemistry, value £150 per annum, are awarded without examination to enable research to be carried on in these subjects. An Arthur Durham Travelling Scholarship of £100 is awarded triennially. The Griffiths Demonstratorship in Pathology of the value of £320 per annum, and the Hilda and Ronald Poulton Fellowship, value £150 per annum, are awarded without examination.

An annual composition fee is paid by all students until a registrable qualification is obtained. Further information may be obtained from the Dean of the Medical School, Guy's Hospital, London Bridge, S.E.1.

#### KING'S COLLEGE HOSPITAL.

The medical school of this hospital, which is situated at Denmark Hill, deals with the advanced or final subjects of the medical curriculum. The hospital was opened in 1913, and is the most modern and best equipped in England. In the education at the hospital a special feature has always been the individual attention given to each student. The studies are co-ordinated under the direction of senior members of the honorary staff, assisted by medical, surgical, obstetric, and pathological tutors. There are special departments for diseases of women and children, nervous diseases, ophthalmology, otology, laryngology and rhinology, dermatology, radiology, and physico-therapy. The laboratory and pathological department are specially noteworthy.

**Appointments.**—Fourteen resident medical and surgical officers are appointed half-yearly, as well as dressers and clerks in the wards, out-patient departments, post-mortem rooms, and special departments. Each of the special departments has several clinical assistants. There are three registrars and four tutors, all of whom receive salaries. The Clubs and Societies Union combines athletics, music, and

other societies connected with the school, and provides also a common room.

**Scholarships, etc.**—At entrance: Science Scholarship, £50. At commencement of Final Studies: Anatomy and Physiology Scholarship, £50; Pathology and Pharmacology Scholarship, £50; two Burney Yeo Scholarships, each £80 (for Oxford and Cambridge students); Epsom College Scholarship, £50; Senior Scholarship, £40; Todd Prize, Tanner Prize, Class Prizes and Medals.

**Fees.**—The composition fee is 93 guineas if paid in one sum. Entrance fee 10 guineas, includes membership of the Clubs and Societies Union.

The calendar of the school can be obtained on application to the Dean, H. Willoughby Lyle, M.D., F.R.C.S., or to the Secretary, S. G. Ranner, M.A., King's College Hospital, Denmark Hill, S.E.5.

#### THE LONDON HOSPITAL.

This hospital, with its medical college and dental school, is situated in the Mile End Road, E.1. The hospital contains 950 beds, and during 1922, 17,441 patients passed through the wards and 107,455 out-patients received treatment. Of the latter number, 32,427 received treatment in the departments for diseases of the ear, nose, throat, eye, skin, and teeth, and in the orthopaedic, venereal, radiological, electro- and physico-therapeutical and inoculation departments. The number of major operations which were performed amounted to 7,215.

The hospital presents, therefore, a large field for clinical instruction, and in its wards and out-patient and special departments exceptional opportunities are afforded for acquiring an extensive and practical experience of all phases of disease.

The clinical units in medicine and surgery co-ordinate the teaching of their subjects in the hospital. The directors and their assistants give practical instruction in elementary clinical medicine and surgery to all students before they are allowed to enter the wards and out-patient department. Senior students are encouraged to work with the units. Special courses of lectures and demonstrations are arranged in medicine and surgery and in their ancillary subjects. Opportunities for research are provided under the supervision of the staffs of the units.

All the departments are modern and adapted for the teaching of all subjects in the various curricula. Special courses of instruction are held in preparation for the examinations of the University of London, for the Fellowship of the Royal College of Surgeons, and for the Membership of the Royal College of Physicians. A course of post-graduate training is held in the work of school clinics for school medical officers (actual and intending) and others. Special entries can be made for the medical and surgical practice of the hospital. A residential hostel on hospital ground is provided for the convenience of students who wish to live near the wards and casualty departments. The athletic ground, of over thirteen acres, is at Highams Park, and is open to all members of the Clubs Union.

**Appointments.**—The salaried appointments open to past students of the Hospital are those of assistants to the clinical units, medical registrars, surgical registrars, obstetric registrar; medical, surgical, and obstetric tutors; clinical assistants in the medical, surgical, ophthalmic, aural, light and skin, orthopaedic, and electrical departments, and in the Pathological Institute. There are appointed annually 4 resident accoucheurs, 14 resident house-physicians, and 24 resident house-surgeons, 14 resident receiving-room officers, 8 resident emergency officers, 8 clinical assistants to the medical out-patient department, and 16 clinical assistants to the surgical out-patient department, also paid and unpaid in clinical assistants in the various special departments. In addition, there are numerous assistantships, clerkships, and dresserships in the departments of medicine, surgery, gynaecology, and obstetrics.

**Scholarships and Prizes.**—The following is a list of scholarships and prizes:—At Entrance: Price Scholarship in Science, £100; Price Scholarship in Anatomy and Physiology, open to students of Oxford and Cambridge Universities, £52 10s.; Entrance Scholarship in Science, £50; Epsom Scholarship, "Free Medical Education." After Entrance: Ruxton Prize in Anatomy and Physiology, £31 10s.; Letheby Prizes in Organic Chemistry and Chemical

DIPLOMAS AND DEGREES.

LONDON UNIVERSITY.—Tropical medicine is one of the six branches in which the M.D. degree may be obtained. The regulations relating to the curriculum and examination correspond to those applying to the other branches.

LONDON CONVOY BOARD.—This body grants a diploma in tropical medicine to candidates after an examination usually held in the months of April, July, and December. Ordinary candidates must present evidence of having attended, subsequently to obtaining a registrable qualification in medicine, surgery, and midwifery, (1) practical instruction in pathology, protozoology, helminthology, entomology, bacteriology, and recognized for this purpose, during not less than three months; (2) the clinical practice of a hospital recognized for the study of tropical diseases during not less than three months. These conditions may be modified in the case of candidates who have had practical experience in tropical countries. The fee for admission to the examination is £9 5s. The Board also grants diplomas in psychological medicine and in ophthalmic medicine and surgery. Candidates must hold a medical qualification registrable in the United Kingdom or be graduates in medicine of an Indian, Colonial, or foreign university. Particulars and conditions of admission to these examinations, fees, etc., may be obtained from the Secretary of the Examining Board, Examination Hall, Queen Square, Bloomsbury, London, W.C.1.

[UNIVERSITY OF LIVERPOOL.—A diploma in tropical medicine is given by this university to students who have been through the courses provided by the Liverpool School of Tropical Medicine and have passed the examination held twice yearly by the university examiners. The subjects of examination are (a) tropical pathology, parasitology, and entomology; (b) tropical and applied bacteriology; (c) tropical hygiene and sanitation; (d) tropical medicine, including etiology, symptoms, diagnosis, and treatment of tropical diseases. Further information can be obtained from the Dean of the Faculty of Medicine, University of Liverpool.

[UNIVERSITY OF CAMBRIDGE.—This university grants a diploma in tropical medicine and hygiene to any person whose name has been on the *Medical Register* for not less than a year provided that he passes the examination of the university in this subject. Previous to admission to the examination he must produce approved evidence that he has studied pathology (including parasitology and bacteriology) in relation to tropical diseases, clinical medicine and surgery at a hospital for tropical diseases, and hygiene and methods of sanitation applicable to tropical climates. Examinations are held in January and August each year, and last four days. The fee for the examination and diploma is 9 guineas on admission or readmission. Application for further information should be made to Dr. G. S. Graham-Smith, Pathological Laboratory, Cambridge.

SCHOOLS.

LONDON SCHOOL OF TROPICAL MEDICINE.—This school is under the auspices of the Seamen's Hospital Society. The laboratories, museum, library, etc., are within the building of the Hospital for Tropical Diseases, Endsleigh Gardens, N.W.1, and excellent opportunities are afforded to students and others who may be desirous of studying diseases incidental to tropical climates before entering the services or going abroad. In the wards of the Hospital for Tropical Diseases are to be found cases of tropical diseases such as may be met with in actual practice in the tropics. There are three courses in the year, lasting three months, beginning September 25th, January 5th, and April 24th approximately. The course is so arranged as to equip men for the Cambridge D.T.M. and H. and D.T.M. and H. of the Conjoint Board. Tropical Medicine has been admitted as a sixth alternative subject for the M.D. of the University of London, and the school curriculum is adapted to afford facilities for candidates desirous of taking the M.D. in this subject. Further information may be obtained from the Dean, London School of Tropical Medicine, India Office, Whitehall, London, and the Secretary, London School of Tropical Medicine, Seamen's Hospital, Greenwich, S.E.10.

PSYCHOLOGICAL MEDICINE.

It cannot be impressed too strongly upon the medical student that a knowledge of mental disorder is just as essential as a knowledge of the other forms of disease which he will be called upon to treat in the routine of general practice. It must be understood that by the term mental disorder is not only meant those severe forms which are to be found in asylums, but the term also includes mental defectives of all grades; nervous, difficult, and backward children; the mild and often unrecognized psychoses; and also the various types of psychoneuroses. Such disorders provide the general practitioner with a large proportion of his most difficult cases, and he will find a good knowledge of mental disorder invaluable in his work. Apart from general practice, the student who proposes to take up a career in the prison service or, still more importantly, the school medical service, will find a knowledge of psychological medicine an almost essential part of his equipment.

At the present time the instruction given to the student is far from adequate to supply the knowledge of mental disorder requisite for the needs of the general practitioner. The

The new laboratories of the school adjoin the university and the tropical ward of the Royal Infirmary. The dimensions of the building are 162 ft. in maximum length by 84 ft. in width. In addition to the basement, in which are accommodated the photographic department and large storage rooms, there are four floors. The ground floor has: (1) Lecture theatre, with accommodation for about seventy students; (2) library; (3) a spacious museum, with preparation room adjoining. The first floor has twelve rooms, in which are housed the Departments of Tropical Medicine and Entomology. The second floor has the main class laboratory, 69 ft. by 53 ft., excellently lighted, and three other rooms, devoted to the Department of Parasitology. The third floor has a large research laboratory and two research rooms. On the roof is an insectarium, a mosquito-proofed house, and other accommodation.

Since it was instituted the school has dispatched to the tropics thirty-two scientific expeditions, many of the workers having been taken from among its students. The work done by them has been published in twenty-one special memoirs, besides textbooks and numerous articles in the scientific press, also in the *Annals of Tropical Medicine and Parasitology* of the school. In connection with the school are (1) the Lewis Jones Tropical Laboratory, Sierra Leone, which was opened on January 10th, 1922. Further information may be obtained from the Hon. Dean, School of Tropical Medicine, Pembroke Place, Liverpool.

LIVERPOOL SCHOOL OF TROPICAL MEDICINE.—This school is affiliated with the University of Liverpool and the Royal Infirmary of Liverpool. Two full courses of instruction are given every year, commencing about January 6th and September 15th, lasting for the term of about thirteen weeks, and followed by the examination for the diploma of tropical medicine given by the University of Liverpool. Two courses in veterinary parasitology are also given, commencing about the same dates as the diploma courses. In addition to the full courses, an advanced course of practical instruction in tropical pathology and medical entomology, lasting a month, is given every year in June; it is of such a kind as to be very useful to medical men returning from the tropics on short leave. A special course of instruction in entomology, etc., is also given three times a year to officers of the East and West African Colonial Services. Students of the school who do not care to undertake the examination held by the university at the end of each term for the diploma in tropical medicine are given a certificate of attendance has been satisfactory.

Fee.—The fee for the full course of instruction is 20 guineas, with an extra charge of 1 guinea for the use of a microscope, if required. The fee for the Diploma Examination is 5 guineas, for the Advanced Course 6 guineas, and for the course in veterinary parasitology 12 guineas.

their second six months they become "senior" house-physicians and house-surgeons, and are provided with rooms by the hospital authorities, and receive a salary of £80 a year. A resident midwifery assistant, an ophthalmic house-surgeon, a house-surgeon to the skin and venereal department, and a house-surgeon for diseases of the throat, nose, and ear are appointed every six months, and are provided with rooms and receive a salary of £80 a year. Three resident administrators of anaesthetics are appointed, the senior for one year at a salary of £150, and two juniors for six months with a salary at the rate of £80 per annum, and all are provided with board and rooms. An extern midwifery assistant is appointed every three months, and receives a salary of £80 a year.

**Scholarships.**—Four entrance Scholarships are annually awarded after an examination held in September. The subjects of examination and conditions of eligibility for these scholarships are: (1) One scholarship, value £75, in not fewer than two and not more than three of the following subjects, Chemistry, Physics, Botany, Zoology, Physiology, and Anatomy, limited to students under 25 years of age who have not entered on the medical or surgical practice of any London medical school. (2) One scholarship, value £100, in not fewer than three of the following subjects, Chemistry, Physics, Botany, Zoology, and Physiology, limited to students under 21 years of age who have not entered on the medical or surgical practice of any London medical school. (3) The entrance scholarship in Arts, of the value of £100, will be given in Latin and mathematics, with one other language—Greek, French, or German. (4) The Jefferson Exhibition in Mathematics, Latin, and one other language—Greek, French, or German—of the value of £50. The value of the scholarships and prizes is over £900 annually.

Further information and a handbook can be obtained on application to the Dean of the Medical College, St. Bartholomew's Hospital, E.C.1.

#### ST. GEORGE'S HOSPITAL.

This school is at Hyde Park Corner, and is carried on in connexion with St. George's Hospital, an institution having a service of 436 beds, of which 100 are at the convalescent hospital at Wimbledon. It provides for the instruction of its students in the preliminary and intermediate subjects of the curriculum at the teaching centres of London University established at King's College and University College. The school at Hyde Park Corner is devoted entirely to the teaching of clinical subjects, great attention being paid by the members of the staff to individual teaching. A number of special courses are given, in which the requirements of university and all other examinations receive careful attention.

The St. George's Hospital Club consists of an amalgamation club, with smoking and luncheon rooms on the hospital premises, and other students' clubs, with an athletic ground at Wimbledon. Students have the advantage of a well filled library of medical and scientific books. A register of accredited apartments and a list of medical men and others willing to receive St. George's men as boarders may be seen on application to the Dean.

**Appointments.**—Four house-physicians, four house surgeons, and two casualty officers are appointed every six months. The house officers receive salaries at the rate of £50 per annum, in addition to board and residence. The casualty officers are non-resident, and receive salaries at the rate of £200 per annum. After the student has held a house appointment, the following are, among others, open to him: Medical registrarship at £200 per annum; surgical registrarship at £200 per annum; assistant curatorship of the museum, £100 per annum; obstetric assistantship, resident, at £50 per annum; the post of resident anaesthetist at £100 per annum; the posts (2) of junior anaesthetist, each at £30 per annum.

**Scholarships.**—Two university entrance scholarships in anatomy and physiology (90 guineas and £70) are awarded at the commencement of each winter session. This year, in addition to these Scholarships, Exhibitions, each of the value of £40 and up to eight in number, will be awarded to candidates of approved merit in the Entrance Scholarship Examination. The William Brown Exhibition of the value of £135 per annum (tenable for two years) is awarded by examination to a perpetual pupil of the hospital every second year. The William Brown Exhibition is £49 (tenable for three years) is awarded by examination to a perpetual pupil of the hospital every third year. Other prizes to the value of £200 are awarded annually to the students of the hospital.

**Fees.**—First year, £36 15s.; second and third years, £42 each. For the course of clinical study, in the fourth and subsequent years, entrance fee, £10 10s.; annual composition fee, £42. No entrance fee is payable by St. George's students who have studied at King's and University Colleges.

Further information may be obtained from the Dean of the Medical College.

#### ST. MARY'S HOSPITAL.

This hospital and medical school are situated close to Paddington Station (G.W.R.), having on one side a poor district of 500,000 persons, and on the other side the residential district of Kensington and Bayswater. The hospital contains 305 beds, and, by a scheme of affiliation, for teaching purposes, of the Paddington Hospital, Paddington Green Children's Hospital, Maida Vale Hospital for Nervous Diseases, and the Lock Hospital for Venereal Diseases, the teaching facilities extend over 1,000 beds. The athletic ground (10 acres) is situated at Wembley, and can be reached in thirty minutes by a constant service of trains; a large pavilion has recently been erected.

**Clinical Facilities.**—Clinical Units in Medicine and Surgery were established in 1920, and have now been formally recognized by the University Grants Committee, St. Mary's being one of the six medical schools in London which enjoy this privilege. In addition to the lying-in beds at St. Mary's, every student attends a short course at Queen Charlotte's Lying-in Hospital (which is situated near to St. Mary's) before holding a post on the maternity district of the hospital.

**Institute of Pathology and Research.**—Students specially interested in pathology and bacteriology have singular advantages at St. Mary's. The Institute comprises seven special departments, the whole being under the personal direction of Sir Almroth Wright, F.R.S. Three research scholarships of £200 each are awarded annually to students working in the departments of the Institute; and research beds are provided. Clerkships in Pathology and Bacteriology and Chemical Pathology, lasting for a period of three months, are open to students of the fifth year, and enable them to carry out the pathological and bacteriological investigations of the wards, and learn the necessary technique under supervision. Seventy-two of these posts are available annually.

**Complete Curriculum.**—The medical school provides complete courses of instruction, and students can join at once on passing a Preliminary Examination in Arts. Terms begin in October, January, and April.

**Entrance Scholarships.**—Three entrance scholarships of £210 each and one of £26 5s. are awarded annually in July by nomination on the lines of the Rhodes Scholarships.

**Fees.**—Composition fees for entire curriculum (5½ years), £200 in one sum, or £210 by five annual instalments. Composition fee for clinical curriculum (2½ years), 90 guineas in one sum, or 95 guineas by two annual instalments. As an alternative, students may pay an annual fee of 40 guineas, with an entrance fee of 10 guineas.

#### ST. THOMAS'S HOSPITAL.

This school and hospital are situated in Lambeth, on the south bank of the Thames, facing the Houses of Parliament, and form one of the well known architectural features of London.

The school buildings, which are separated from the hospital by a quadrangle, comprise lecture theatres, laboratories, and classrooms well adapted for the modern teaching of large bodies of students in the subjects of the medical curriculum. A splendid library and reading room and a complete museum are open to all students from 9 a.m. to 5 p.m., on Saturdays to 1 p.m. The Students' Club premises contain a dining room and smoking and reading room supplied with daily and illustrated weekly papers, and a gymnasium. Good meals are obtainable at a moderate tariff. The Terrace affords facilities for exercise and recreation. The sports ground, of more than nine acres in extent, is at Chiswick. It can be reached in forty minutes from the hospital; it is admirably adapted for football, cricket, lawn tennis, and athletic sports.

The hospital proper contains 632 beds. In addition to the ordinary provisions of a great hospital there are connected with the out-patient department physicians' and surgeons' rooms provided with ample sitting accommodation, so that

expert knowledge. By the adoption of this suggestion there would be many asylums for two senior assistant medical officers, and perhaps even three or four in the largest asylums.

(A) That except where there has been previous asylum experience, appointments to posts of assistant medical officers should be made with a view to encouraging assistant medical officers to obtain a diploma or degree in mental diseases, including provision for study leave on full salary. The following sentence:

"If the welfare, treatment, and recovery of patients is not to be jeopardized and the study of mental diseases is not to be neglected, the study of other branches of medicine, the Board feel the necessity of instituting measures to maintain progress and to secure the best possible treatment of the patients."

Both the British Medical Association and the Medical Psychological Association are working separately and together to improve present conditions of service, and have, for example, already removed the "cellulacy" objection to the service. The salaries have also been considerably increased, especially in the junior ranks, and contrast favourably with those which were paid before the war. During the next few years considerable progress may be anticipated in the conditions under which the insane are treated. The asylums will tend to develop an atmosphere approximating more closely to that of the general hospitals. If these most desirable changes are brought about, the mental hospital service will become more attractive, and will afford greater opportunities for the medical graduate who proposes to specialize in psychiatry.

It may be said that while routine, administrative, and clerical work bulk largely in mental hospital duties, as they do in other public medical services, there is ample material, time, and scope for purely medical work and research—difficult as the subject may be—in psychiatry as one of the branches of medicine open to young graduates. If the Mental Treatment Bill passes into law, psychiatric work will undoubtedly become still more attractive to medical men. In this bill power is given to local authorities to make provision for the treatment of early and acute cases of mental disorder without certification. When this bill comes into operation hospitals, either in the precincts or the grounds of the county or borough mental hospitals, or in wards in general hospitals may be utilized for the same purpose. Such facilities would render appointments in mental hospitals more attractive, because the work would be entirely free from the custodial aspects of mental disorder, and attention could be given by the physician to purely medical problems without

any of the legal restrictions. A number of courses of instruction for the Diploma in Psychological Medicine have been given at the Maudsley Hospital, the details of the last course being as follows: The course consisted of two parts, Part I being conducted by Sir Frederick Mott, Dr. F. Colla, and Dr. Henry Devine. Sir Frederick Mott gave eight lectures on the anatomy and demonstrations on methods of staining nervous tissue and preparing it for microscopic examination; microscopic sections were distributed, illustrating the principal diseases of the nervous system, for mounting as a permanent collection. Dr. Colla gave eight lectures on the physiology of the nervous system, followed by practical instruction in the chemistry of the nervous system, physico-chemical methods, blood and urine analysis, and gastric contents analysis, and practical physiology (including the recording of reflexes and tremors in man and the action of drugs on the autonomic system). Similarly,

Dr. Devine gave eight lectures on psychology, followed by practical instruction and demonstration of psycho-physical methods and memory and intelligence tests. In Part II of the course Sir Frederick Mott gave six lectures on the pathology of mental diseases, including brain syphilis, its symptoms and treatment. Dr. Bernard Hart gave eight lectures on the psychomotor system, Sir Frederick Mott and Dr. F. C. Shrubsole gave eight lectures on the practical aspect of mental deficiency. Dr. W. C. Sullivan, medical superintendent of Broadmoor Asylum, gave six lectures on crime and insanity. Dr. C. Hubert Bond and Dr. E. M. Mabergh gave a course of lectures on the differential diagnosis and treatment of mental disorders and the legal relationships of insanity. The fee for the whole course (Part I and Part II) was 15 guineas, or for either part separately 10 guineas; for one single series of lectures in Part I the fee was 4 guineas, and in Part II 2 guineas. Inquiries as to lectures, etc., should be addressed to the director of the pathological laboratory, Maudsley Hospital, Denmark Hill, S.E.5.

#### BETHLEM ROYAL HOSPITAL.

A course will be held at Bethlem Royal Hospital, commencing on September 17th, of lectures and practical instruction for the Diploma in Psychological Medicine. It is proposed in future to give two courses each year—an autumn session of intensive character, commencing in September, and completed in early December, and a spring session, commencing in the middle of January and completed in the middle of April. Each course consists of two parts: Part A includes lectures and demonstrations on the anatomy, histology, and physiology of the nervous system, with lectures on psychology and demonstrations in experimental psychology. Part B comprises lectures and clinical demonstrations in psychology, including lectures and demonstrations in the morbid anatomy, and clinical demonstrations in psychiatry, on mental time, and lecture, with clinical demonstrations, on mental deficiency. Entrants for the course who pay a composition fee of 15 guineas may, if due notice is given, attend either Part A or Part B of one course and postpone the other part until the next session. An entrant who wishes to attend one part only pays a fee of 10 guineas. An entrant who takes the complete course can attend the general clinical practice of the hospital on payment of 5 guineas for six months, but an entrant who does not take either part of the course and desires to attend the clinical practice of the hospital must pay a fee of 5 guineas for each of three months of attendance. To enable post-graduate students to obtain special experience in this branch of medicine clinical assistants are appointed from time to time. Further particulars may be obtained from the physician-superintendent, Bethlem Royal Hospital, S.E.1.

#### NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, QUEEN SQUARE.

A post-graduate course, which fulfilled the requirements of the regulations for the Diploma in Psychological Medicine in regard to instruction in nervous diseases, was held at the National Hospital for the Paralyzed and Epileptic, Queen Square, Bloomsbury, W.C.1, from May 7th to June 29th, 1913, and other courses will be duly announced. Dr. J. G. Greenfield delivered lectures on the pathology of the nervous system, various clinical lectures and demonstrations were given, and out-patient clinics were held at the hospital on the afternoons of Mondays, Tuesdays, Thursdays, and Fridays. An inclusive fee of 10 guineas was charged for the whole course, but any part of the course could be taken separately at a special fee. A special arrangement was made for those unable to attend the whole course, and for details applications should be made to the dean of the medical school. Similar courses are held three times a year—namely, January, May, and October. Special arrangements are made throughout the year for work in the laboratory. Fees are payable to the secretary of the hospital on entering for the course.

and to the officers in charge of special departments, are appointed from among the qualified students. Every student must perform the duties of out-patient dresser for four months, and afterwards hold the office of in-patient dresser for four months. He is also required to serve two terms of four months each as medical clinical clerk to in-patient physician and one term as gynaecological clinical clerk. Two pathological clerks are appointed every three months to assist in the post-mortem room. No student is eligible as an in-patient dresser or clinical clerk until he has passed the Second Examination of the Conjoint Board, or an equivalent examination. Clerks and dressers in the special departments of hospital practice are periodically appointed. So far as vacancies permit, students of other hospitals are admitted to in-patients' dresserships or clerkships.

**Scholarships.**—The following open scholarships are offered for competition during the year 1923-24: In the winter session two scholarships in anatomy and physiology, £70 each. In the spring two scholarships in anatomy and physiology, £70 each. A certain number of scholarships have been allotted to universities of England, Wales, and the Colonies, and to public schools. These scholarships are awarded entirely on the nomination of the Principal of the University or School.

**Fees.**—The annual composition fee is 35 guineas. An entrance fee of 10 guineas is payable by all students—namely, primary and intermediate students, £10 10s.; students entering for the final subjects, £8 8s. These fees include subscriptions for membership of the Clubs Union.

Further information and a prospectus can be obtained on application to the Dean at the Westminster Hospital, Westminster, S.W.1.

The Governors of the Hospital propose in the near future to carry out extensive improvements and alterations to the Hospital which will render it a still more efficient teaching institution.

#### LONDON (ROYAL FREE HOSPITAL) SCHOOL OF MEDICINE FOR WOMEN.

The school is situated at 8, Hunter Street, Brunswick Square, W.C.1, close to the Royal Free Hospital. It is, like all the other London schools which have so far been mentioned, one of the constituent schools of London University. The school buildings have recently been enlarged. The laboratories are extensive and well lighted, and are fully equipped for the examination courses of the University of London and the Royal Colleges of Physicians and Surgeons. Research laboratories are attached to all departments. A large, well equipped library, common room, Union room, and refectory are provided for the use of students. Resident accommodation for 58 students is provided in students' chambers attached to the school.

The Royal Free Hospital, Gray's Inn Road, W.C.1, has 240 beds, all of which are available for clinical instruction. A new block contains the Obstetrical and Gynaecological Unit, which, with the Marlborough Maternity Department, controls 68 beds. There are separate departments for diseases of the eye, ear, and skin, infant welfare, venereal diseases, massage, electrical and x-ray work, dentistry, and casualty. The instruction given covers the full curriculum for the M.B., B.S. degrees of the University of London, including first medical courses. Students attend the practice of one of the fever hospitals of the Metropolitan Asylums Board and receive special instruction in lunacy at Bethlem Hospital; they are also admitted to the practice of a number of special hospitals, and hold clerkships and dresserships at the Elizabeth Garrett Anderson Hospital, the Cancer Hospital, Hospital for Sick Children, the National Hospital for Nervous Diseases, the South London Hospital, and the Royal Ophthalmic Hospital. The work of the school includes preparation for the Primary Fellowship examination, and also for the medical school and general hospital course for dental students. An agreement has also been made under which a certain number of students of the school can receive clinical instruction at St. Mary's Hospital, Paddington.

**Appointments.**—Qualified students of the school can obtain appointments as house-physicians and house-surgeons, obstetric assistants, surgical, gynaecological, and medical registrars, assistant pathologists, assistant anaesthetists.

medical electrician, skiagrapher, and clinical assistants and demonstrators in various subjects.

**Scholarships.**—The Isabel Thorne Entrance Scholarship, value £30, the St. Dunstan's Medical Exhibition, value £60 a year for three years, which may be extended to five years, and the Mabel Sharran-Crawford Scholarship value £20 a year for four years, are offered for competition in each year. The Sir Owen Roberts Memorial Scholarship of the value of £75 a year for four years, the Mrs. George M. Smith Scholarship of the value of £50 a year for three years, which may be extended to five years, the Dr. Margaret Todd Scholarship of the value of £37 10s. a year for four years, and the Sarah Holborn Scholarship of the value of £20 a year for three years, which may be extended to five years, are awarded in alternate years. The Bostock Scholarship, value £90 a year for two or four years, is awarded by the Reid Trustees on the result of an examination held in May by the University of London every fourth year. The holder of the scholarship must enter the London School of Medicine for Women. The Lieutenant Edmund Lewis and Lieutenant Alan Lewis Memorial Scholarship, of the value of £25 a year for four years, is awarded every fourth year. The John Byron Bursary of £20 a year for two years, the Helen Prideaux Prize of £40, the Mabel Webb Research Scholarship of £30 for two years, the Fanny Butler Scholarship of £14 10s. a year for four years, together with many other scholarships and prizes, are offered on sundry conditions. The Dr. Edith Pechey-Phipson Post-Graduate Scholarship of £100 is awarded annually. Various missionary societies also offer scholarships on certain conditions, and assist ladies who wish to go to India and other countries as medical missionaries.

**Fees.**—Courses for the University of London degrees and the diplomas of the Conjoint Board in England, and other qualifications: £240, payable in five instalments. These sums include library and laboratory fees.

The Students' Union exists to promote corporate action of the students on matters of common interest, to promote and maintain athletic and other clubs, and to issue a school magazine. All students are required to become members of the Union.

Further information can be obtained from the Warden and Secretary.

#### KING'S COLLEGE.

In the Faculty of Medical Science instruction is given in the preliminary and intermediate subjects of the first and second examinations leading to the degree of M.B., B.S. of the University of London, of the corresponding examinations of other universities, and of the Conjoint Examining Board of the Royal Colleges of Physicians and Surgeons, including the primary examination for the F.R.C.S. Eng. The courses are open to women students on the same terms as to men.

Regular students who have completed their preliminary and intermediate examinations proceed to a hospital to pursue their studies for the final examinations. The hospitals associated with King's College are: King's College Hospital, Denmark Hill, S.E.5; Westminster Hospital, S.W.1; St. George's Hospital, Hyde Park Corner, S.W.1; and Charing Cross Hospital, Strand, W.C.2.

There is a Department of Public Health and Bacteriology under the direction of Sir William J. Simpson and Professor R. T. Hewlett. Full particulars of this department may be obtained from the Secretary of the College.

A course for the diploma in dental surgery in conjunction with King's College Hospital Medical School has been arranged. Full details may be obtained on application to the Secretary, King's College Hospital Medical School, Denmark Hill, S.E.5.

**Scholarships.**—The entrance Scholarships are: (1) Two Warnford Scholarships, each £30 for four years; subjects—selected from mathematics, classics, divinity, and science. (2) One Sambrook Exhibition of £25 for two years, open; subjects of examination—mathematics, elementary physics, inorganic chemistry, botany, zoology, and geology. The holders of the preceding awards must proceed to King's College Hospital. (3) Worsley, £100, paid in five annual instalments. (4) Rabbeth Scholarship, value £20, in July, for the best student of the first year. (5) Second year's scholarship, value £20, for the best student of the second year. (6) Daniell Scholarship, £40, awarded on the results of the University Honours Examination.

Full information as to admission, fees, and scholarships can be obtained from the Dean of the Faculty of Medical Science (Professor E. Barclay-Smith), King's College, Strand, W.C.2.

the inspection imposed by law of benefit not merely to the individual child but to the community at large, by preventing conditions which lead to the existence of a large proportion of inefficient citizens among the adult population. In short, the work is so far related to that of a medical officer of health that in most areas the senior school medical officer, his both appointments, his work, when necessary, being supplemented by that of whole- or part-time assistants. Whole-time assistants are commonly paid salaries commencing at a minimum of £500 a year, the chief attraction of the posts being that they may lead on to appointment as medical officer of health, but we fear that not many actually do reach that position. Yet it is desirable for a prospective whole-time school medical officer to obtain a diploma in public health. In some counties and county boroughs it is now the practice for the officer to undertake classes when necessary, the removal of adenoids, and treatment in connection with certain diseases of the skin. The added interest thus given to the work appears to make for increased efficiency and also enhances the value of the post. Otherwise the monotony of filling up record cards in the absence of any duty of treatment is apt to become intolerable, and if no public health functions belong to the post it gives little chance of developing into a health officership.

#### TUBERCULOSIS OFFICERS.

Before sanatorium benefit was transferred to the public health authorities the prescribed duties of tuberculosis officers were to act as advisers to Insurance Committees in connexion with the operation of the National Insurance Act and to take charge of the work of the tuberculosis dispensary, which is the main unit of the Departmental Committee's scheme. A tuberculosis officer is a whole-time officer, who should have special training in tuberculosis work, and be of suitable age and attainments to command general confidence. At present the number of appointments is small, and the salary generally attached to them is about £300 a year with an occasional bonus addition. In many instances they are now appointed on the staff of the medical officer of health, so that the work of prevention and cure of tuberculosis may be made part of the general health work of the Municipal Council.

Schemes for the diagnosis and treatment of venereal diseases are administered by county councils and borough councils. A few of these authorities have appointed whole-time medical officers at a salary of £500 to £700 per annum. In some cases the officer is on the staff of the medical officer of health and in others he is an independent official. Specialized practical experience in the treatment of venereal diseases is essential, and it is an advantage if such experience has been obtained in the navy or army. His duties usually include not only the diagnosis and treatment of cases of venereal disease at one or more central clinics, but also the instruction and supervision of the treatment by general practitioners attached to local clinics.

#### DIPLOMAS IN PUBLIC HEALTH.

New rules for study and examination for these diplomas come into force on January 1st, 1924, but it will be convenient in the first place to state the present position. Most of the universities and licensing corporations now grant diplomas in public health to candidates who pass the examinations imposed by them. Since all such tests must conform to the requirements of the General Medical Council, there is considerable similarity in their nature, though they differ not a little in their reputed difficulty. All of them aim at excluding any candidate who does not appear to have a thorough knowledge of his work in theory and in practice, for the regulations of the General Medical Council demand that the granting of a diploma in Sanitary Science, State Medicine, or Public Health shall be proof of the "possession of a distinctive high proficiency, scientific and practical, in all the branches of study which concern the public health." The tests, in short, are supposed to constitute an honour and not a mere pass examination. As regards the special tuition required, it is

#### Existing Rules.

It is desirable to note in this connection that the chemical and bacteriological examinations for many of the health diplomas are so practical, and the time allowed so short, that unless a candidate—even though familiar with the duties of M.O.H.—has a considerable amount of manipulative dexterity only to be acquired by ample work in a laboratory, he would not be likely to satisfy the examiners.

The present rules of the General Medical Council remain in force until January 1st, 1924. They require that every candidate (subsequently to obtaining a registrable qualification in medicine and surgery) shall have passed through a varied curriculum in the subjects of sanitary science. This must last not less than nine calendar months, and include four months' study in a laboratory in which chemistry, bacteriology, and the pathology of diseases of animals transmissible to man are taught, six months' practical study of the duties involved by public health administration, and attendance at least twice weekly for three months on the practice of a hospital for infectious diseases at which instruction is given in methods of disinfection. These rules do not apply to practitioners registered or entitled to be registered before January 1st, 1890, while that regarding six months' practical study of public health administration is waived in the case of a candidate who has himself been in charge of a sanitary district with a population of not less than 15,000 for a period of not less than three years. The study in question must be passed under the personal supervision of a medical officer possessing certain definite facilities for affording it, these being carefully described in the regulations. The period may be reduced to three months in the case of a candidate who has undergone a corresponding period of study in the public health department of a recognized medical school, or who has been resident medical officer at a hospital for infectious diseases with accommodation for 100 patients for not less than three months. The laboratory study must include at least 240 hours' work, not more than half being devoted to practical chemistry. The examinations imposed by the diploma-granting bodies must extend over not less than four days, one at least being devoted to practical work in the laboratory, and one to practical examination in, and reporting on, subjects within the duties of a medical officer of health, including those of a school medical officer.

The steps which examining bodies take to ascertain the candidate's fitness for a diploma are in all cases much the same, though the order in which the subjects are taken is not always identical. Every candidate therefore should, when he has settled what diploma or degree in State medicine he wishes to obtain, seek the schedule relating to it from the authority concerned. A certain number of the universities grant degrees in the subject as well as diplomas.

#### The New Rules.

The new Rules will apply after January 1st, 1924. They require that not less than two years shall elapse after obtaining a registrable qualification before admission to the Final Examination for a public health diploma. The curriculum shall extend over not less than twelve calendar months. At least five months must be given to practical laboratory instruction in an approved institution in (a) bacteriology and parasitology, including entomology, especially in relation to diseases of man and to those transmissible to man from the lower animals (150 hours); (b) chemistry and physics in relation to public health (90 hours); and (c) meteorology and climatology (10 hours). Not less than 50 hours' instruction in an approved institution, or by approved teachers, must be given to the following subjects, the approximate hours being as bracketed: Principles of public health and sanitation (30), epidemiology and vital statistics (20), sanitary law and administration (20), sanitary construction and planning (10).

There is required three months' attendance—30 daily attendances of not less than two hours in each week—on the clinical practice of a recognized hospital for infectious diseases, with instruction in methods of administration. Six months' practical training under a medical officer of health is an important feature of the new scheme, and the time cannot be reduced by attendance on lectures as at present. Three hours on each of six working days are the minimum, and the instruction is to include maternity and child welfare, the services relating to school life, venereal disease and tuberculosis, industrial hygiene, and food, meat, and milk inspection. The examination will consist of two parts, each lasting for at least two days. Part I covers bacteriology, parasitology, and climatology. Part II includes hygiene and sanitation, epidemiology and infectious diseases, sanitary laws and vital statistics, and public health administration. There will be practical examinations in medicine (after registration in medicine) have been completed, and Part I must be passed before admission to Part II.

## BRISTOL.

The school is carried on by the Faculty of Medicine of the university, and provides full instruction for all its degrees and diplomas. The allied hospitals (Bristol Royal Infirmary and Bristol General Hospital) have between them about 600 beds and extensive out-patient departments, special clinics for diseases of women and children, and those of the eye, throat, and ear, in addition to arrangements for dental work and large outdoor maternity departments. At each of these institutions there are well arranged pathological departments, comprising large pathological museums, *post-mortem* rooms, and laboratories for morbid anatomy. There are also laboratories for work in clinical pathology, bacteriology, and cytology, in which special instruction is given in these subjects. Departments are provided and well equipped for x-ray work both in diagnosis and treatment, the various forms of electrical treatment, including high-frequency currents, electric baths, Finson light treatment, and massage.

The students of the school have also the advantage of attending the practice of the Royal Hospital for Sick Children and Women, containing 108 beds, and that of the Bristol Eye Hospital, with 40 beds. Excellent facilities are thus afforded to students for obtaining a wide and thorough acquaintance with all branches of medical and surgical work. Each student has the opportunity of personally studying a large number of cases and acquiring practical skill in diagnosis and treatment. All classes are open to women.

**Appointments.**—(1) Undergraduate: Clinical clerkships, dresserships, also ophthalmic, obstetric, pathological, ear, nose and throat clerkships, are tenable at the Bristol Royal Infirmary and the Bristol General Hospital. In these institutions the dressers reside in rotation free of charge. (2) Post-graduate—At the Bristol Royal Infirmary: Four house-surgeons, £120 each per annum; two house-physicians, £120; resident obstetric and ophthalmic house-surgeon, £120; throat, nose and ear house-surgeon, £120; dental house-surgeon, £120. All these appointments are made for twelve months. From the resident officers a senior resident officer is appointed at a salary of £200. At the Bristol General Hospital: Senior resident medical officer, £300 per annum; casualty house-surgeon, £125 per annum; two house-physicians, £125 per annum; house-surgeon, £125 per annum; special obstetric physician, £125 per annum; house-surgeon to special departments, £125 per annum; dental house-surgeon, £300 per annum. All these appointments are for six months, except that of senior resident medical officer, which is for two years.

**Scholarships.**—The following are among the scholarships and other awards open to students of the school: The Ashworth Hallott Scholarship, value £15, open to women only; two Martin Memorial Pathological Scholarships of £10 each; the Tibbits Memorial Prize, value 9 guineas, for proficiency in practical surgery; the Committee's Gold and Silver Medals for fifth-year students for general proficiency; the Augustin Prichard Prize, value 7 guineas, for proficiency in anatomy; the Henry Clark Prize, value 11 guineas, for proficiency in gynaecology; the Crosby Leonard Prize, value 7 guineas, for proficiency in surgery; the Supple Surgical Prize, a gold medal and 7 guineas; the Supple Medical Prize, a gold medal and 7 guineas; the Henry Marshall Prize, value £12, for dressers; the H. M. Clarke Scholarship, value £15, for proficiency in surgery; the Sanders Scholarship, value £22 10s., for general proficiency; the Barrett-Roué Scholarship for proficiency in diseases of the eye, ear, nose and throat, value £14.

**Fees.**—The fee for all the courses required for the medical curriculum, including hospital practice, is 205 guineas, paid by annual instalments.

## UNIVERSITY COLLEGE OF SOUTH WALES AND MONMOUTHSHIRE.

*The Welsh National School of Medicine.*

STUDENTS can complete the whole of their curriculum in the school. The courses of instruction are fully adapted to meet the needs of those students studying for the degrees in Medicine and Surgery of the University of Wales, and certain of them also for the degrees of other universities and for the diplomas of the Conjoint Board. All classes are open to both men and women students.

Medical men wishing to prepare for the Diploma in Public Health or the Tuberculosis Diploma, etc., can do so at the

Prospectuses can be obtained on application to the Faculty of Medicine, or to Mr. D. J. A. Brown, at University College, Cardiff.

UNIVERSITY OF DURHAM COLLEGE OF MEDICINE. This, the Medical School of the Faculty of Medicine of the University of Durham, is in the neighbouring city, North-Don-Tyne. Its classes and lectures are arranged to requirements of the university in all the degrees with latter grants, and also those of the other examining bodies. The students do their work in the preliminary school at Armstrong College, also part of the university, and clinical work in the Royal Victoria Infirmary, in connection with about 550 beds and special accommodation for the benefit of students. In a Heath wing of the school there is the department of physiology. There are also this wing a gymnasium and a set of rooms for the Students' Union. A new bacteriological department recently been erected adjacent to Armstrong College.

**Appointments.**—Assistant demonstrators of anatomy, prosectors for the professor of anatomy, assistant pathologists, pathological assistants, and assistants in the department, throat and ear department, and department of skin diseases, are elected periodically. Clinical clerks and dressers are appointed every three months.

**Scholarships.**—A University of Durham Scholarship, value £100 a year for four years, for proficiency in arts, open annually at the beginning of the winter session to intending students. The Dickinson Memorial Scholarship, value £150, for proficiency in arts (when won) and a gold medal for medicine, surgery, midwifery, and pathology, open to perpetual students in their fifth year. The Tulloch Scholarship, interest of £400 annually, for elementary anatomy, biology, chemistry, and physics, for students at the end of their first year. The Charlton Memorial Scholarship, interest of £700 annually, open to full students entered for the class of medicine, at the end of the fourth or fifth winter. The Gibb Scholarship, interest of £100 annually, for pathology, at the end of summer session. The Prizo, interest of £250 stock, for midwifery. Outtersen Prize, interest of £250, for psychological medicine. The George Memorial Scholarship, proceeds of £325; subjects: clinical medicine and clinical surgery. Luke Armstrong Memorial Scholarship, proceeds of £680, for best essay in some subject in comparative pathology. The Stephen Scott Scholarship in Surgery, interest of £1,000 annually. The Heath Scholarship in Surgery, of the value of £200, awarded every other year. First award in 1896. Philip Scholarships (2), the interest on £1,800, to the candidates who obtain the highest marks in the Final M.B., B.S. examinations held in March and June respectively.

**Fees.**—The composition fee for lectures at the college is £1. Composition fee for hospital practice, £46, plus £2 2s. yearly for three years, payable to the Committee of the Royal Victoria Infirmary. Other information should be sought from the Registrar of the College of Medicine at Newcastle.

## LEEDS.

THE School of Medicine—which is open to both male and female students—in this city forms the teaching centre of the Medical Faculty of the University of Leeds, and is situated in immediate proximity to the General Infirmary. The students sufficiently advanced receive instruction in the buildings. The buildings were opened in 1894, and contain excellent dissecting rooms, several well arranged laboratories for physiology, pathology, and bacteriology, three lecture theatres, and several similar classrooms. In addition, there are a library and reading room and two museums, one being devoted to pathology and the other to anatomy. The comfort of the students is secured by common rooms and a refectory in which they can take meals. The General Infirmary has 632 beds, and includes gynaecological and ophthalmic wards, a special children's ward, and a large out-patient department. The Ida and Robert Arthington Semi-convalescent Hospitals, Cookridge, attached to the Infirmary, have 88 beds. The West Riding Lunatic Asylum at Wakefield is also open for the study of mental diseases. Students can, in addition, attend the practice of the Leeds Public Dispensary (where the practical instruction in dental subjects is also given).

SEPT. 1, 1923] ROYAL AIR FORCE

chemistry. Two Entrance Scholarships in Medicine, value 160 guineas, awarded annually for proficiency in Arts or Science respectively. One Research Fellowship in Public Health of £100, awarded annually. Tom Jones Exhibition in Anatomy, £25, offered annually. A Robert Platt Physiological Scholarship of £90, tenable for one year. A Leech Fellowship of £100 for original research after graduation. A Graduate Scholarship in Medicine, value £25, tenable for one year, awarded annually for proficiency shown at Final M.B. Examination. A Dunville Surgical Prize, value £15, awarded annually at graduation. The Tom Jones Memorial Surgical Scholarship, value £80, tenable for one year, awarded usually annually. The Turner Medical Prize, value £20, in certain subjects of the Final M.

John Henry Agnew Scholarship of £30, awarded annually for proficiency in the Diseases of Children. The Ashby Memorial Scholarship, tenable for one year (£100), for research in the Diseases of Children; offered triennially. Sidney Redshaw Exhibition in Physiology; one offered annually. The details and regulations of the Dickinson Scholarships—(1) for Anatomy, (2) for Pathology, (3) Research Scholarship in Surgery, and (4) Travelling Scholarship in Medicine—may be obtained from the Secretary to the Trustees. The Sam Gamble Scholarships—the trustees are prepared to award four scholarships of not less than £10 per annum, tenable for not more than four years, to women students who have passed the first M.B. Examination; the conditions can be obtained from the Registrar. The Knight Prize of £50 for original research in the psychological factors in the causation of mental disorder—open to holders of the Diploma in Psychological Medicine or medical practitioners who have been registered in the university as candidates for that diploma.

**Fees.**—The composition fee for the university course in medicine is 104 guineas, payable in four instalments of 26 guineas, but this sum does not include the fee to cover the work required for the first M.B. Examination. This is 36 guineas, payable in one sum. Hospital fees are additional and usually amount to about 77 guineas.

A prospectus and further information about the school and scholarships may be obtained from the Registrar.

**Clinical Work.**—The Royal Eye Hospital, the Hospital for Diseases of the Skin, the Manchester Northern Hospital for Women and Children, the well known Hospitals for Children at Pendlebury, and St. Mary's Hospital for Diseases of Women and Children, all make arrangements for the instruction of students.

#### SHEFFIELD.

In this city the Medical School is one of the departments of the University, being conducted and controlled by its Medical Faculty, and occupying practically the entire north wing of the quadrangle of the university buildings overlooking Weston Park. The laboratories and lecture rooms connected with the subjects of the first and second examinations—namely, chemistry, physics, biology, anatomy, and physiology—are, both as regards structural arrangement and scientific equipment, on the most modern and complete lines.

For students of pathology and bacteriology there are laboratories replete with everything necessary for the most advanced work, and a large pathological museum which is open daily. In addition, there is a museum devoted to materia medica specimens, and a large library and reading room. There are a number of recreation, athletic, and other societies, all under the management of an annually elected students' representative council, and large and comfortable common rooms both for men and women students. In the university buildings there is a refectory open to all students of the school, and a university journal is published each term. The ordinary clinical work of the school is done at the Royal Infirmary and Royal Hospital, which have amalgamated for the purpose of clinical instruction, and provide over 500 beds for medical, surgical, and special cases, including diseases of the eye.

In addition, the Royal Infirmary has special departments for the treatment of diseases of the skin and ear, with beds assigned to them; whilst at the Royal Hospital there are special out-patient departments for diseases of the throat, ear, skin, orthopaedics, and mental diseases. The medical and surgical staffs attend daily, and give clinical instruction in the wards and out-patient rooms. Clinical lectures in medicine and surgery are given weekly. Instruction in the practical administration of anaesthetics is given at either institution by the anaesthetists, and the *post-mortem* examinations at both institutions are in charge of the Professor of Pathology, and afford ample material for study of this subject. Students are able to attend the practice of the Jessop Hospital for Diseases of Women and the Hospital for

Sick Children, while special courses on fever are given at the City Fever Hospital, and on mental diseases at the South Yorkshire Asylum.

**Appointments.**—The following appointments are open to all students who have passed their examinations in anatomy and physiology: (1) Casualty dresserships, (2) surgical dresserships, (3) medical clerkships, (4) pathological clerkships, (5) ophthalmic clerkships, (6) clerk to the skin department, etc. These appointments are made for three months, commencing on the first day of October, January, April, and July.

**Scholarships.**—Entrance Medical Scholarship, value about £100, open to both sexes. Four Edgar Allen Scholarships of £125 a year for three years may be held by students taking the degree course in Medicine. Two Town Trustees' Scholarships, each of the value of £50, tenable for three years, for boys or girls under the age of 19 years who have been educated in a Sheffield secondary school for a period not less than two years immediately preceding the examination. Four Town Trustees' Scholarships, value £50, for boys or girls under 19 years of age, educated in any school in Sheffield, secondary or otherwise. Town Trustees' Fellowship, value £75, tenable for one year. Mechanics' Institute Fellowship, value £50 (with remission of fees), tenable for one year, and renewable for a second year. The Frederick Clifford Scholarship, value about £50, tenable for two years. Kaye Scholarship, for proficiency in anatomy and physiology, value £22 10s. Gold and bronze medals are also awarded for proficiency in various subjects.

**Fees.**—Students in the Faculty taking their complete medical course in the university pay an inclusive composition fee of £33 for each of the five years. Students taking a complete dental course pay a composition fee of £25 at the beginning of each year of the course. In addition, a fee of £50 is payable each year the student receives instruction in Mechanical Dentistry in the Dental Department. The fees for special courses taken separately can be ascertained by inquiry of the Dean.

#### SCOTLAND.

As will be gathered from the following paragraphs, the facilities for acquiring a medical education in Scotland are very ample, whether the student be proceeding to a university degree or to a diploma. To the descriptions of the different Scottish medical centres is in some cases added an account of hospitals which either play an official part in the education given to students as yet unqualified or offer valuable opportunities for post-graduation work.

#### ABERDEEN.

The school is conducted by the Faculty of Medicine. This comprises twelve chairs, from which instruction is given in all the main branches of medical science—namely, botany, zoology, physics (ordinary and pre-registration), chemistry (ordinary and pre-registration), anatomy, physiology, materia medica, pathology, forensic medicine, surgery, medicine, and midwifery. Courses of instruction in public health, tropical medicine, medical ethics, and sanatorium treatment of tuberculosis, are conducted by lecturers appointed by the University Court. Special opportunities for practical instruction are afforded in the laboratories and museums attached to the departments.

Clinical instruction is obtained in the Royal Infirmary (accommodating 270 patients), the Royal Lunatic Asylum (900 patients), the Sick Children's Hospital (85 patients), the City Fever Hospital (250 patients), the General Dispensary, Maternity, and Vaccine Institution (10,000 out-patients annually), and the Ophthalmic Institution (3,000 patients annually). Courses of practical instruction are given in diseases of children at the Sick Children's Hospital; in fevers at the City Fever Hospital; in insanity at the Royal Asylum; in diseases of ear, nose, and throat at the Infirmary and Dispensary; in diseases of the eye at the Infirmary and Eye Institution; in venereal diseases and diseases of the skin at the Royal Infirmary.

The degrees granted in medicine are: Doctor of Medicine (M.D.), Master of Surgery (Ch.M.), Bachelor of Surgery and Bachelor of Medicine (M.B., Ch.B.). A Diploma in Public Health is conferred after examination on graduates in medicine in any university of the United Kingdom.

The degree of Ph.D. is also granted in this faculty. Bursaries, Scholarships, and Fellowships, to the number of fifty and of the annual value of £1,180, may be held by students

because facilities for transfer from the medical service of one colony or group of colonies to that of another are as yet practically non-existent, except in connexion with a few specialist and senior appointments; this sets strict limits upon the opportunities for promotion.

The bulk of the medical appointments made by the Secretary of State in this country are to the services in the East and West African Colonies and Protectorates, the Straits Settlements and Malay States, the East Indies, and Fiji and the Western Pacific. In general, candidates for such appointments must be between the ages of 23 and 35; and whilst these limits are not for the moment absolute, an officer over 35 years of age on first appointment may be required to serve on a temporary and non-pensionable footing; regular appointments are, subject to a varying period of probation, for the most part, nominally at least, permanent and pensionable. There is no entrance examination, but practitioners selected for appointment must obtain a certificate of physical fitness from one of the Medical Advisers of the Colonial Office. In the case of the West African Medical Staff and the East African Services successful candidates are required to undergo an approved course of instruction in tropical medicine.

**Colonial Service: The General Outlook.**

While colonial service offers undoubted attractions to some practitioners it also presents very definite disadvantages, and not the least of these is, at the present time, uncertainty as to the future. Before the war, conditions in several of the services gave rise to considerable anxiety; the greatly enhanced cost of living during the war resulted in certain more or less inadequate temporary advances in remuneration, but consideration of the radical reforms required was postponed until the succeeding period of reconstruction. In 1919 a Departmental Committee under the Chairmanship of Sir Walter Egerton was appointed to consider the position of the Services generally, the means of securing contentment within them, and the maintenance and increase of the supply of candidates. The Committee found that the ideal to be aimed at was the creation of a unified Colonial Service, recruited by competitive examination and represented on the staff of the Colonial Office by a Medical Director-General. As an immediate step in this direction it recommended the assimilation of the medical services in neighbouring colonies, and more especially those in the East African and Malayan groups. A permanent increase of salaries with a general minimum of not less than £600 a year on first appointment was recommended; the necessity for study leave was recognized, as was the need for the development of facilities for research; an increase in the number of specialist appointments and adequate provision for promotion by transfer from the service of one colony or group to that of another were other points emphasized.

Progress along these lines laid down by the Departmental Committee, which corresponded broadly to the policy adopted by the British Medical Association, has undoubtedly been made since the report of the Committee was issued. With the exception of the West Indian Services, the Fiji and Pacific Colonies, and a few of the smaller dependencies which each offer only one or two medical appointments, the adoption of the £600 minimum or its equivalent in local coinage has been achieved. The commencing pay in the West African Medical Staff is £600 a year. For all practical purposes the Services in the Malay Peninsula have been unified, and some steps have been taken towards the assimilation of the East African Services, whilst there has been an appreciable increase in the number of specialist appointments and the facilities for research. The Services, however, remain undisturbed on one service to another without loss of pension, must remain inadequate. Certain services, notably those in the West Indies and Fiji, have not yet secured that measure of reform essential to a minimal standard of efficiency, and it seems that the final unification of the East African Medical Services under conditions approximating to those of the West African Medical Staff will be indefinitely postponed.

Moreover, the acute economic depression of the last three years has affected many of the colonies with almost crushing poverty. It has in some cases brought about the indefinite postponement of projected reform, and in others it has practically neutralized advances in remuneration that were at one time thought to be permanent, besides imposing disastrous restrictions on the public health programme in many places, and reductions in the medical personnel of the Services. Not do economic difficulties, radical though they are, stand alone. The constitutional status of the colonies is under review. Schemes for regrouping and for the concession of greater local autonomy may be temporarily delayed pending economic recovery, but it is not unreasonable to suppose that until such questions are settled there can be little progress towards the unification of the Colonial Medical Service. Their adoption, on the other hand, may entail the formulation of a new solution for the admitted difficulties.

The condition of the Colonial Medical Services has for some time been a matter of the gravest concern to the British Medical Association, which gave evidence on the subject before the Egerton Committee, and has been in constant communication with the Colonial Office on matters touching their welfare since August, 1921. During this period the Association has, in effect, been recognized as the mouthpiece of the Services, and has received copies of all official documents primarily affecting medical officers, and also the gazettes of the various local Governments. It has therefore been possible to supplement the activities of the Overseas Branches by the exercise centrally of unceasing vigilance over all tendencies likely to affect the development of the Colonial Services. It cannot be too strongly emphasized, however, that present conditions render advance impracticable.

The future is extremely uncertain, and after twelve months record we must again warn intending candidates to consider carefully whether they may not be well advised to look elsewhere than to the Colonial Medical Services for a career.

**Kenya Colony and the Windward Isles.**

The necessity for caution is not diminished by the action of the Secretary of State for the Colonies in connexion with the recent reduction of personnel in the Kenya Colony Medical Service. The ruling in this case, discussed in detail in the *British Medical Journal* of April 21st last, by which two established members of the service were compulsorily retired without compensation beyond the award of the pension payable after the same period of service, in the event of retirement on grounds of ill health, has made it plain that colonial appointments officially scheduled as permanent and pensionable do not, as a matter of fact, afford security of tenure. Doubtful as the general outlook is, it is bright in comparison with the conditions now obtaining in the Windward Islands, where three years of unremitting effort on the part of the British Medical Association, both centrally and locally, have ended in failure. The Representative Body of the Association, after full consideration of the facts of the case, and with a due sense of the responsibility involved in any action tending to hinder the supply of qualified candidates for the services in these islands, passed at Portsmouth last July a resolution regretting that the Colonial Office had declined to press the claims of the Windward Islands Medical Officers with regard to their terms and conditions of service, and thoroughly endorsing the action taken by the Council in support of those claims. Such a resolution is the best possible commentary upon the opinion already expressed in these columns (June 30th, 1923, p. 1102), that no qualified medical practitioner aware of the conditions of service will accept an appointment in these islands.

All inquiries in connexion with colonial medical appointments made by the Secretary of State for the Colonies should be addressed to the Assistant Private Secretary (Appointments) at the Colonial Office, and information can be obtained at the same address. Vacancies also occur, though at rare intervals, in the Sudan, and inquiries as to these should be addressed direct to the Civil Secretary, Sudan Government, Khartoum. Inquiries about any medical appointments made by the Egyptian Government should be addressed to the Director-General, Public Health Department, Cairo.

Information as to medical appointments in the self-governing Dominions and their dependencies can be obtained on application to the High Commissioners or Agents-General for the Dominions. Intending applicants are also recommended to

The following bursaries are open to undergraduates of both sexes: The Gibson Bursary, annual value £30, tenable for four years. This is open to medical students who are preparing for service as medical missionaries in connexion with the Church of Scotland and will be awarded to the eligible candidate who has gained the highest number of marks in the First Professional Examination. The Arbnoath Bursary, annual value £10, tenable for three years, is awarded by the Senate, on the recommendation of the Faculty of Medicine, to the student who is of the highest merit among the candidates, as shown by their class records and their performances in the First and Second Professional Examinations. One Logan Bursary, annual value £16, tenable for four years; appointment by the Senate. Six Lorimer Bursaries (each £20 and tenable for one year) are awarded to the best students in each of the following classes: botany, zoology, physics, chemistry, anatomy, physiology. The Mackintosh Mental Science Bursary in medicine, of the value of £31, is awarded annually to the student (of either sex) attending the class of insanity who stands first in an examination in that subject, the bursar to continue the practical study of the subject to the satisfaction of the Faculty of Medicine. The Gardiner Bursary, annual value £14, tenable for two years, will be awarded after the autumn professional examination to the candidate who has passed in physiology at the Second Professional Examination, and whose aggregate of marks in that subject and in chemistry and physics of the First Professional Examination is the highest. Of the eight James A. Paterson Bursaries two are awarded each year; they are of the value of £30 and £20 respectively, and are tenable for four years; examination in mathematics and natural philosophy in June for students entering the first and second year of medical study. The following are tenable in any faculty: Four Nivison Bursaries (each £75 and tenable for four years), two Pratt Bursaries (each £20 and tenable for four years), and two Taylor Bursaries (each £10 and tenable for four years). Andrew and Bethia Stewart Bursaries (£50 each, tenable for three years); candidates must have taken the M.A. degree of Glasgow. There is a special examination. Nino Glasgow Highland Society's Bursaries, for students of Highland descent, of the annual value of £25, and tenable for five years; two vacant each year.

The Carnegie Trust for the Universities of Scotland is empowered to pay the whole or part of the university ordinary class fees of students of Scottish birth or extraction, under conditions given in the *University Calendar*. The Dobbie Smith Gold Medal is awarded for the best essay on a prescribed subject within the science of botany. The Brunton Memorial Prize of £10 is awarded annually to the most distinguished graduate in medicine of the year. The University Commissioners issued an ordinance to make regulations for the admission of women to certain bursaries, scholarships, and fellowships. Scholarships and fellowships are offered by the Carnegie Trust in science and medicine for post-graduation study. There are also four McCunn Medical Research Scholarships (two of £200 and two of £100) for graduates in medicine of the Scottish universities; one Faulds Fellowship for Research in Medical Science of approximately £200 for three years; and one Strang Steel Scholarship value £160 for one year.

**Fees.**—The matriculation fee for each year is £2 2s. In most cases the fee for each university class is £6 6s., but in some cases it is £1 4s. For hospital attendance students pay an entrance fee of £7 at the Western Infirmary, with an additional fee of £5 5s. for each winter and £2 12s. 6d. for each summer clinical course; at the Royal Infirmary the fees are somewhat similar. The university fee for the four professional examinations is £34 13s. For the whole curriculum the fees for matriculation, class attendance, hospital attendance, and professional examinations amount to about £225.

For further information apply to the Registrar, Glasgow University.

**QUEEN MARGARET COLLEGE.**—In this, the Women's Medical School of the University of Glasgow, the courses of study, degrees, regulations, fees, etc., are the same as for men. Women students have their own buildings, with classrooms, reading room, library, etc. They are taught in some classes apart from male students, in others together with them, but in either case have all the rights and privileges of university students. Their clinical studies are taken in the Royal Infirmary, where wards containing 520 beds are available for their use, and in its dispensary; and similarly in the Western Infirmary and in the Victoria Infirmary; also in the Royal Hospital for Sick Children, the Glasgow Ear Hospital, the Royal Asylum, Gartnavel, Hawkshead Asylum; the Ophthalmic Institution, the City of Glasgow Fever Hospitals, Belvidere and Ruchill; and the Glasgow Royal Maternity and Women's Hospital.

**Scholarship.**—The Arthur Scholarship, annual value £20, tenable for three years. Open to competition by medical students of first year at the First Professional Examination in October, 1922. This scholarship is restricted to women medical students.

Full information can be obtained from the Mistress, Margaret Hospital.

**Board for Students.**—A house of residence for women students, Queen Margaret Hall, is situated near the castle in Bute Gardens. The cost of board and residence is 27s. to 32s. 6d. a week, according to accommodation. Attention to be made to the Lady Superintendent. A hostel near the college is South Park House, Ann St., belonging to the Student Christian Movement, and open to women students of all colleges in Glasgow. Cost of board from 28s. to 30s. weekly. Applications to be made to the Warden.

**ST. MUNGO'S COLLEGE.**—This is the Medical School of the Royal Infirmary, which is the largest general hospital in Glasgow. The infirmary is situated in Cathedral Square, Castle Street, and has car communication with every part of the city. St. Mungo's College is in the infirmary grounds and affords full courses in all the subjects of the medical curriculum, and in all the medical subjects of the dental curriculum.

The infirmary has (including the ophthalmic department) over 700 beds, the average number occupied in 1920 being over 600. There are special beds and wards for diseases of women, of the throat, nose and ear, venereal diseases, burns and septic cases. In the out-patient department the attendances in 1921 numbered 168,610. In addition to the large medical and surgical departments, there are departments for special diseases—namely, diseases of women, of the throat and nose, of the ear, of the eye, of the skin, and of the teeth. There is also a fully equipped electrical pavilion, with the latest and most approved apparatus for diagnosis and treatment.

**Appointments.**—Five house-physicians and eleven house-surgeons, who must be fully qualified, are appointed every six months, and board in the hospital free of charge. Clerks and dressers are appointed by the physicians and surgeons. As many cases of acute diseases and accidents of a variety of character are received, these appointments are very valuable.

**Fees.**—The average class fee is £3 3s. for summer classes and £4 4s. for winter classes. The fees for all the lectures, practical classes, and hospital attendance necessary for candidates for the diplomas of the English or Scottish Colleges of Physicians and Surgeons amount to about £80. The classes are open to male and female students.

A syllabus of classes can be obtained on application to the Secretary to the Medical Faculty, St. Mungo's College, 86, Castle Street.

**THE ANDERSON COLLEGE OF MEDICINE.**—This school provides education in all subjects of the curriculum for both medical and dental students. The school buildings are situated in Dumbarton Road, immediately to the west of the University and Western Infirmary. The hospital practice and clinical lectures are provided in the Western or Royal Infirmary; pathology in the Western or Royal Infirmary; vaccination and dispensary practice in the Western or Royal Infirmary Dispensary. These classes are recognized by all the licensing corporations in the United Kingdom, also by the Universities of London, Durham, Glasgow, and Edinburgh (the latter two under certain conditions stated in the school Calendar). The courses (lectures and laboratory) in public health are recognized by the Scottish Licensing Board, the Universities of Oxford, Cambridge, and London, and the London and Irish Colleges.

**Fees.**—The fees for the lectures and practical work required by ordinary students range between 2 and 5 guineas a session. In the Public Health Department the fee for a six months' course is £14 14s. The Carnegie Trust pays the fees of students at Anderson College on conditions regarding which particulars may be obtained from the Secretary, Carnegie Trust Offices, Edinburgh.

A Calendar will be sent on receipt of a postcard by the Secretary to the Medical Faculty, the Anderson College of Medicine, Glasgow, W., who will forward any further information which may be desired.

The Royal Samaritan Hospital for Women, Glasgow, with over 90 beds, offers facilities for clinical instruction in the diseases peculiar to women. Particulars may be obtained from J. Mason Macquaker, M.A., honorary secretary, 149, St. Vincent Street, Glasgow.

majority of the directors and all the operating staff are registered business ancillary to dentistry is carried on by the company. Companies carrying on the business of dentistry at the present time are permitted to continue to do so with certain restrictions, provided that the names of the directors have been entered in a list kept by the registrar for the purpose. Every director or manager of a company convicted of an offence under the act will be held to be guilty of the offence unless he proves that the offence was committed without his knowledge, and the court may, in addition to a fine, order that the name of any director convicted shall be removed from the list of directors aforesaid.

#### THE DENTAL BOARD.

The Dental Board of the United Kingdom has been established for the purpose of administering the new act. The first members hold office for three years, subsequent members for five years. The Privy Council has appointed the chairman and two members, the latter being dentists not registered under the principal act. The General Medical Council has appointed three members, who must be members of the Branch Council for England, Scotland, and Ireland respectively. Three persons who are neither medical practitioners nor dentists represent England, Scotland, and Ireland, and four registered and qualified dentists have been appointed—two by the Minister of Health, one by the Scottish Board of Health, and one by the Lord Lieutenant of Ireland. At the end of three years the two members being dentists not registered under the principal act, and the four members of Health (two), the Scottish Board of Health, and the Lord Lieutenant of Ireland, will be replaced by four members who will be elected by qualified dentists practising in the three countries and two by registered dentists who are not qualified. On the establishment of the Dental Board in 1921 certain powers and duties of the General Medical Council were transferred to it, including the duty of erasing from the *Dentists Register* any entry which has been incorrectly or fraudulently made. An inquiry into the case of a person alleged to be liable to have his name erased from the *Register* will be made by the Board, which will report its finding to the General Medical Council, the order directing the erasure being made, as at present, by the Council upon a report made by any person aggrieved either by refusal of the Board to register his name or by the removal of his name from the *Register*. The first registrar was appointed by the General Medical Council with the approval of the Privy Council, and he holds office for three years; subsequent appointments will be made by the Board. The administrative expenses of the Board are defrayed from the registration fees and annual retention fees, but any surplus may be allocated to purposes connected with dental education and research or to any public purpose connected with dentistry. The office of the Dental Board is at 44, Hillman Street, London, W.1.

The *Dentists Register* for 1923 contains the names of 12,762 persons, of whom less than a half are registered with qualifications, 7,689 names having been registered under the *Dentists Act*, 1921.

#### DENTAL EDUCATION AND EXAMINATION.

The preliminary examination in Arts is the same for medical and dental students, and the early stages of their education embrace much the same subjects; and, as the dental student is required to obtain a knowledge of the broad principles of medicine and surgery, it is necessary for him to pursue some portion of his studies at a medical school as well as at a special dental school, the latter not undertaking the teaching of these subjects. Registration as a dental student is not in all cases compulsory, though it is to be advised as convenient as affording proof of the commencement of professional education, and it is required by most of the licensing bodies, all of whom insist upon a curriculum covering four academic years.

Qualifying licenses are granted by the Royal Colleges of Surgeons of England and of Edinburgh and of Ireland; by the Royal Faculty of Physicians and Surgeons, Glasgow; and by certain of the universities in the United Kingdom.

See the *Registrar's Memorandum*, printed in the article on the General Medical Council at page 336.

1. That every dental student shall, at the commencement of his studies, be registered in the manner and under the conditions prescribed for medical students.

2. That before registration in the *Dental Students Register* every applicant shall be required to have passed, in addition to the examination in general education, which shall be the same as that required for medical students, an examination in Elementary Physics and Chemistry, conducted or recognized by one of the licensing bodies, which shall also be the same as that required for medical students.

3. That before registration as a dental student every applicant shall produce evidence that he has attained the age of 17 years.

4. That every candidate for a degree or license in dentistry or dental surgery shall be required before admission to the final or qualifying examination to produce certificates showing:

(i) That he is at least 21 years of age.

(ii) That he has been registered as a dental student.

(iii) That he has, subsequently to the date of registration as a dental student, been engaged in professional study for at least four years, of which three years at least shall be spent at a school or schools recognized for professional study by one of the licensing bodies.

(iv) That, subsequently to the date of registration as a dental student, he has attended at a recognized medical school courses of instruction in the following subjects: (a) Human Anatomy (with dissections and demonstrations) for three academic terms; (b) Physiology (with laboratory instruction, including practical Histology) for two academic terms; (c) General Pathology (including Bacteriology) for two academic terms; (d) Medicine for two academic terms; (e) Surgery for two academic terms; (f) General Pathology and Clinical Histology and Morbid Histology. The course should comprise a minimum of twenty meetings of the class.

(v) The practice of a recognized dental history and Morbid Histology. The course should comprise a minimum of sixteen meetings of the class.

(vi) That he has attended at a recognized dental school courses of instruction in the following special subjects: (a) Dental Anatomy (with dissections and demonstrations) for two academic terms; (b) Dental Physiology and Pathology for two academic terms; (c) Dental Histology and Morbid Histology for two academic terms; (d) Dental Materia Medica and Therapeutics. The course should comprise a minimum of twenty meetings of the class.

(vii) That he has attended at a recognized dental school courses of instruction in Clinical Medicine and Clinical Surgery, for four academic terms.

Recommendations of the General Medical Council.

The Dental Act still leaves to the General Medical Council the duty of controlling the course of study and examinations required for dental qualifications.

The following recommendations as to the course of study and examinations to be required of candidates for degrees or licenses in dentistry or dental surgery were adopted by the Council on May 27th, 1922.

1. That every dental student shall, at the commencement of his studies, be registered in the manner and under the conditions prescribed for medical students.

2. That before registration in the *Dental Students Register* every applicant shall be required to have passed, in addition to the examination in general education, which shall be the same as that required for medical students, an examination in Elementary Physics and Chemistry, conducted or recognized by one of the licensing bodies, which shall also be the same as that required for medical students.

3. That before registration as a dental student every applicant shall produce evidence that he has attained the age of 17 years.

4. That every candidate for a degree or license in dentistry or dental surgery shall be required before admission to the final or qualifying examination to produce certificates showing:

(i) That he is at least 21 years of age.

(ii) That he has been registered as a dental student.

(iii) That he has, subsequently to the date of registration as a dental student, been engaged in professional study for at least four years, of which three years at least shall be spent at a school or schools recognized for professional study by one of the licensing bodies.

(iv) That, subsequently to the date of registration as a dental student, he has attended at a recognized medical school courses of instruction in the following subjects: (a) Human Anatomy (with dissections and demonstrations) for three academic terms; (b) Physiology (with laboratory instruction, including practical Histology) for two academic terms; (c) General Pathology (including Bacteriology) for two academic terms; (d) Medicine for two academic terms; (e) Surgery for two academic terms; (f) General Pathology and Clinical Histology and Morbid Histology. The course should comprise a minimum of twenty meetings of the class.

(v) The practice of a recognized dental history and Morbid Histology. The course should comprise a minimum of sixteen meetings of the class.

(vi) That he has attended at a recognized dental school courses of instruction in the following special subjects: (a) Dental Anatomy (with dissections and demonstrations) for two academic terms; (b) Dental Physiology and Pathology for two academic terms; (c) Dental Histology and Morbid Histology for two academic terms; (d) Dental Materia Medica and Therapeutics. The course should comprise a minimum of twenty meetings of the class.

(vii) That he has attended at a recognized dental school courses of instruction in Clinical Medicine and Clinical Surgery, for four academic terms.

Recognized dental schools are numerous. In London there are the National Dental Hospital (now the University College Hospital), Guy's Hospital, and the London Hospital. In the provinces there are the Birmingham Dental Hospital; the Royal Infirmary and the General Hospital, Bristol; the Dental Hospital and the Public Dispensary, Leeds; the Dental Hospital, Liverpool; the Dental Hospital, Manchester; the Dental Hospital, Newcastle-on-Tyne; the Royal Hospital, Sheffield. In Scotland there are the Dental Hospital, Dundee; the Incorporated Dental Hospital, Glasgow; and in Ireland, and the Incorporated Dental Hospital, Dublin.

of the new university, but students proceeding for the examinations of the Conjoint Board of England, Scotland, or Ireland, the Society of Apothecaries of London, or the Apothecaries' Hall of Ireland, or London University, can arrange the courses of lectures which they attend, and the order in which they attend them, to meet the requirements of those bodies. Certificates of attendance at the college courses are also accepted by the University of Cambridge. Clinical instruction is given at the North and South Infirmarys (each 100 beds) and at the Cork Union Hospital (1,200 beds). Students can also attend the Mercy Hospital (60 beds), the County and City of Cork Lying-in Hospital, the Maternity, the Hospital for Diseases of Women and Children, the Fever Hospital, the Ophthalmic and Aural Hospital, and the Eglinton Lunatic Asylum. The session extends from October to June.

There is a Dental School in which the degree of Bachelor of Dental Surgery of the National University of Ireland can be obtained. There is a large well equipped dental hospital in connexion with the school.

**Scholarships.**—Over £1,000 are available annually for scholarships in the College. Particulars as to each of them can be obtained on application to the Registrar.

**Fees.**—The fees for the lectures and hospital attendances required by the National University of Ireland course, including examination fees, come to about £150.

Further information can be found in the college regulations, or obtained on application to the Registrar.

#### UNIVERSITY COLLEGE, GALWAY.

This institution is one of the constituent colleges of the National University of Ireland, and includes Faculties of Art, Science, Law, Celtic, Engineering, Commerce, and Medicine. The college buildings are well lighted and well ventilated, and contain dissecting rooms, an anatomical theatre, and laboratories for the study of physiology, chemistry, physics, and other departments of medical science. For pathology and chemistry new laboratories are now provided. It has good grounds surrounding it, and there are many arrangements, such as a library, a college union, and an athletic union, for the benefit of those belonging to the Medical Faculty, as well as for students in other departments of the college. The clinical teaching, which is recognized as qualifying not only for the degrees of the National University, but for those of London University and the diplomas of the various colleges in the three kingdoms, is carried on at the Central Hospital, Galway County Hospital, the Galway Fever Hospital, and the Galway Dispensaries. The Galway Central and County Hospitals are general hospitals, and at the other two hospitals and at the dispensaries students have ample opportunities of studying zymotic and chronic diseases. The Central Hospital has a special ward for diseases of children. Each year the governing body offers about £1,500, and the County Councils of Connaught offer about £3,500, in scholarships. These scholarships are tenable in any faculty. Additional information regarding these scholarships can be obtained on application to the Registrar, and to the Secretaries of the Connaught County Councils.

### CLINICAL HOSPITALS IN ENGLAND.

THERE are a great many hospitals in Great Britain and Ireland which, though not connected with any medical school, open their doors either to those who have yet to become qualified, to those who are doing post-graduation work, or to both. The facilities they offer for gaining practical clinical experience are very great, and should not be overlooked. Their honorary staffs commonly make a point of giving such instruction as opportunity offers, and at those situated in the larger towns there are often appointments as clinical assistants to be obtained. In addition, they all have to offer, at shorter or longer intervals, appointments for resident medical officers, house-physicians, and house-surgeons. These are usually paid offices, which may be held for periods varying from six months to a year. Some of those situated in the great medical centres in the provinces, and in Scotland and Ireland, have already been mentioned in speaking of the medical schools in these localities, but it should be added

that there are many other provincial hospitals where admirable work is done, and at which much valuable experience can be gained by both senior and junior students, and by those already qualified. Cases in point are the Royal Infirmary, Bradford; the Royal Sussex County Hospital, Brighton; the Royal United Hospital, Bath; the Kent and Canterbury Hospital; Derbyshire Royal Infirmary; the Royal Albert Hospital and Eye Infirmary, Devonport; the Royal Devon and Exeter Hospital; the West of England Eye Infirmary, Exeter; the Gloucestershire Royal Infirmary and Eye Institution; the Royal Infirmary, Leicester; the County Hospital, Lincoln; the General Hospital, Northampton; the Norfolk and Norwich Hospital; the General Hospital, Nottingham; the Royal Portsmouth Hospital; the Royal Berks Hospital, Reading; the Royal South Hants and Southampton Hospital; the Staffordshire General Infirmary, Stafford; the North Staffordshire Infirmary at Hartshill; the Royal Hants County Hospital, Winchester; the Wolverhampton and Staffordshire General Hospital; the County Hospital, York; and the Coventry and Warwickshire Hospital.

#### London Clinical Hospitals.

As for the hospitals in the metropolis, so many of these take a share in the giving of clinical instruction that it is worth while to classify them.

**General Hospitals.**—These include the Dreadnought Hospital at Greenwich, and its annexe at the Albert Dock, which form the headquarters of the London School of Clinical Medicine, and the London School of Tropical Medicine with its hospital at Endsleigh Gardens; the West London Hospital and the Prince of Wales's General Hospital, Tottenham, both of these being described in the article on post-graduate work; the Royal Northern Hospital, Holloway Road, an institution containing 185 beds; and the Temperance Hospital in Hampstead Road.

**Children's Hospitals.**—There are at least seven of these, the leader among them being the Hospital for Sick Children, Great Ormond Street, which has 240 beds. There are also the East London Hospital for Children, Shadwell, with 124 cots; the Queen's Hospital for Children, Bethnal Green, with 134; the Victoria Hospital for Children, Chelsea, with 104; the Belgrave Hospital for Children, which has a considerable out-patient department, but in-patient accommodation for only 40 children; the Paddington Green Children's Hospital, an institution of about the same size; and the Evelina Hospital for Sick Children, Southwark Bridge Road, with 76 beds.

**Hospitals for Women.**—Queen Charlotte's Lying-in Hospital, Marylebone Road, with 70 beds and a residential college for students and practitioners, specializes in the teaching of midwifery. The Samaritan Hospital for Women, Marylebone Road, admits qualified practitioners as clinical assistants to both the in-patient and out-patient departments; demonstrations are given daily in both departments, the fees—payable in advance—being £3 3s. for three months; full particulars may be obtained from the secretary. In addition may be mentioned the Hospital for Women, Solo Square, whose teaching is confined to post-graduates in limited numbers; the Chelsea Hospital for Women, Arthur Street, Chelsea; and the Elizabeth Garrett Anderson Hospital for Women in Euston Road, the latter being in the nature of a general hospital so far as concerns the class of case treated.

**Eye Hospitals.**—The largest of these is the Royal London Ophthalmic Hospital (Moorfields), City Road. At this hospital two complete courses of instruction are given during the year—October to February and March to July—comprising the following subjects: anatomy, physiology, and optics; ophthalmic medicine and surgery—(1) external diseases, (2) motor anomalies and squint, (3) ophthalmoscopic conditions (weekly classes), (4) pathology; practical refraction classes; methods of examination (practical); operative surgery; practical pathology; practical bacteriology; x-ray and radiotherapy; clinical lectures; discussion classes. A fee of 24 guineas entitles the holder to one full five months' course (with the exception of practical pathology and practical bacteriology), together with a permanent ticket for the practice of the hospital. Fee for the practice of the hospital (permanent), £5 5s.; for three or six months, £3 3s.; for two months, £2 2s.; for one month, £1 1s. Gentlemen are eligible, under certain conditions, for the posts of chief clinical assistant, clinical assistant, and junior assistant. Clinical work takes place every morning at 9 o'clock, and operations at 10 every morning. An additional special course in the preliminary subjects (namely, anatomy, physiology, and optics) for the D.O.M.S., and other ophthalmology examinations, will be held immediately preceding the date of the examination. The fees for this course will be 12 guineas, or £5 5s. for any subject separately. Further particulars may be obtained from the Dean of the Medical School. Other eye hospitals are the Royal Westminster Ophthalmic

# Dependable Ligatures

## LONDON HOSPITAL CATGUT

The sterility of every batch is verified by bacteriological control, both aerobic and anaerobic tests being carried out.

The time factor of absorption is practically constant, and can be guaranteed in every grade.

The tensile strength is such that even in the finest gut there is a wide margin of safety. Every batch of London Hospital Catgut is tested by a specially designed machine which accurately registers the breaking strain.

STERILITY

ABSORPTION

TENSILE STRENGTH

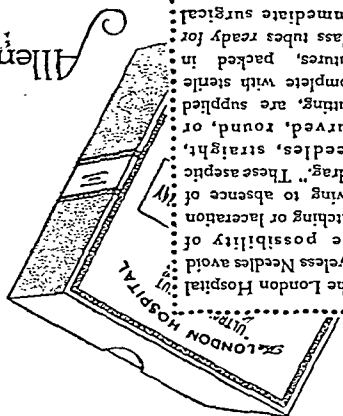

"Ultran" Catgut is prepared under the strictest aseptic conditions in the special laboratories which have been set up for the purpose at the London Hospital, and is in use in the 15 operating theatres there. The unique feature is that sterilisation commences immediately after the splitting of the intestine before the gut is twisted. This ensures that no contaminating debris (which almost invariably would escape sterilisation) is enclosed within the turns, later to become the focus of infection at the site of operation.

The fact that "Ultran" Catgut is made at the London Hospital and is continually in use there, ensures of excellence which cannot be assured with any other ligature or suture.

*Descriptive Book-let will be sent post free upon application to the Sole Distributors:*

Allen & Hanburys Ltd.  
48, WIGMORE ST.,  
LONDON, W.1.

The London Hospital Eyeless Needles avoid the possibility of catching or laceration owing to absence of "drag." These aseptic needles, straight, curved, round, or cutting, are supplied complete with sterile sutures, packed in glass tubes ready for immediate surgical use.

Professional Matriculation Examination is open to ministers of religion, barristers and solicitors, medical practitioners, registered teachers; also to engineers, architects, surveyors, pharmacists, accountants, auditors, and associates of the Institute of Bankers, holding recognized qualifications conferred after examination. Information should be sought from the Registrar, The University of London, South Kensington, S.W.7.

#### UNIVERSITY OF DURHAM.

The degree of M.D. is granted by the University of Durham to registered practitioners of not less than fifteen years' standing, who have been qualified and in practice for that period, upon the following conditions, without residence: The candidate must be 40 years of age, and must produce a certificate of moral character from three registered medical practitioners. Should he not have passed an examination in arts previously to the professional examination in virtue of which his name was placed on the Register, he is examined in classics and mathematics; if otherwise, he is required to translate into English passages from any one of the following Latin authors: Caesar, *De Bello Gallico* (first three books), Virgil, *Aeneid* (first three books), or Celsus (first three books). Natives of India or the British Colonies are placed on the same footing as natives of Great Britain. Natives of India must produce evidence from an Indian university that they have passed within one year an examination in Latin.

**Professional Examination.**—The candidate must pass an examination in the following subjects: (i) Principles and practice of medicine, including psychological medicine, hygiene, and therapeutics; (ii) principles and practice of surgery; (iii) midwifery and diseases of women and children; (iv) pathology, medical and surgical; (v) anatomy, medical and surgical; (vi) medical jurisprudence and toxicology. The examination is conducted by means of printed papers, clinically, and *viva voce*, at the College of Medicine, Northumberland Road, Newcastle, and in the Royal Victoria Infirmary. The classical part of the examination may be taken separately from the professional on payment of a portion (£10 10s.) of the full fee.

The examinations are held twice a year, towards the end of March and of June. Notice, accompanied by the fee and certificates, must be sent to Professor Howden, Registrar of the University of Durham College of Medicine, Newcastle-on-Tyne, at least twenty-eight days before the commencement of the examination.

**Fees.**—The inclusive fee is 50 guineas; if a candidate fail to pass, 20 guineas are retained, but if he present himself again, 40 guineas only are required.

#### UNIVERSITY OF BRUSSELS.

Until recently this university granted its M.D. to such foreign candidates as were already duly qualified in medicine and surgery in their own countries, provided they passed the three special examinations imposed. The examinations were conducted *viva voce*. The University of Brussels, however, announced two years ago that these special examinations would no longer be held, nor would the M.D. Brussels diploma be granted by the university to foreign medical practitioners as formerly. Nevertheless, we are informed by the Secretary of the University, Dr. Jean Willems, that it is still possible for a foreigner to obtain in Brussels a diploma of "Docteur en médecine, chirurgie et accouchements," which, although it does not entitle to practise in Belgium, has exactly the same value as the Belgian legal diploma.

For Belgians (Dr. Willems writes) the usual length of studies is seven years: two years of candidature of sciences, two years of candidature of medicine, and three years of doctorate of medicine. But it rests with the Faculty concerned to decide on questions of equivalence of foreign academic records with the ordinary Belgian qualifications for admission to university courses, so that a student who has several years of university training in Great Britain may, on presentation of his certificates or diplomas, be admitted to follow the courses of the first, second, or even third doctorate. I beg to insist on one point which if properly understood may spare your citizens much useless trouble. It happens that English practitioners, already bearers of an M.D. diploma, ask from the Faculty that our degree of doctor be conferred on them *ad eundem* on payment of necessary fees. The regulations of our University absolutely forbid that a diploma be granted to anybody, without at least one year's attendance on the courses.

## POST-GRADUATION STUDY.

### THE POSITION IN ENGLAND.

It is unfortunate that so far very little success has attended efforts made to establish in England a predominant centre of post-graduate education. There is no lack of material for post-graduate study, and teachers are plentiful. But of real organization capable of affording facilities such as exist even in post-war Vienna there is very little evidence. In any such organization two objects must be held in view; first, provision for study which will attract men of capacity from the Dominions, America, and foreign countries; secondly, courses which will benefit practitioners in this country whether they intend to perfect themselves in special forms of treatment or to bring up to date their knowledge of general subjects in medicine and surgery.

A committee appointed by Dr. Christopher Addison, when Minister of Health, under the chairmanship of the Earl of Athlone, did something to crystallize ideas on the subject of post-graduate education. This committee recommended that a school attached to a hospital centrally situated in London should be devoted solely to post-graduate medical education, that it should be a school of the University of London, and that it should receive financial assistance from Parliament. On the other hand, many have held that a hospital entirely devoted to post-graduate students need not for the moment be regarded as essential to a post-graduate scheme; and that a central co-ordinating body for post-graduate students might, with the material already available, lay the foundation of a scheme of which a post-graduate hospital might ultimately come to be the centre.

These views have been discussed by the Fellowship of Medicine, a body which arose in 1918 for the purpose of drawing together the members of all the inter-allied countries for the exchange of medical knowledge and the advancement of medical science. The Fellowship of Medicine arranged a post-graduate course in the early part of 1919 for the benefit of medical men who had served as temporary officers in the Royal Navy, the R.A.M.C., the Royal Air Force, and from the Dominions, the United States, and the allied countries. The Fellowship of Medicine was amalgamated with the Post-Graduate Medical Association in October, 1919, and since that date the combined body has applied itself to the problem of establishing a predominant post-graduate institution in London. It cannot, however, be said that its efforts so far have brought it within sight of success. The main result of its deliberations up to the present has been a reconstitution of the Fellowship of Medicine as representative of a number of hospitals which are not engaged in undergraduate teaching. While the reconstituted body will doubtless be of great value in meeting the needs of practitioners in this country, it is hardly likely to carry the prestige which will place England in the forefront as a centre of post-graduate education.

So far, however, as medical practitioners in this country are concerned, whether they be newly qualified or wishful to refresh their knowledge or to embark on special treatment, the facilities offered are numerous and varied, even if somewhat unco-ordinated. The Fellowship of Medicine, in addition to possessing an office, kindly housed at the Royal Society of Medicine, 1, Wimpole Street, for the provision of information regarding post-graduate facilities, has organized courses of instruction at various hospitals scattered about London. The monthly *Bulletin* of the Fellowship contains a list of the hospitals which welcome the attendance of graduates. For those who desire to revise or increase such medical knowledge as is useful in their professional work, the West London Post-Graduate College and the North-East London Post-graduate College are eminently suitable. Some of the large undergraduate teaching hospitals provide short post-graduate courses for their former students during the summer vacation. The London Panel Committee arranges with Guy's Hospital for periodical courses of demonstration lectures to be given to insurance practitioners, and at Charing Cross Hospital weekly post-graduate classes are held. At the London Hospital there are courses in connexion with school clinics. Courses in special diseases are obtainable at a large number of special hospitals, a list of which is printed in the *Handbook for Recently Qualified Practitioners*, issued by the

VICTOR BOWEN, M.S., M.D., F.R.C.S., President.

## DISCUSSION ON THE TREATMENT OF ACUTE

## SALPINGITIS.

INTRODUCTORY PAPERS.

I.—ALECK W. BOURNE, B.Ch., M.B., F.R.C.S.,

Obstetric Surgeon for Out-patients, St. Mary's Hospital.

In this paper our discussion will be confined to the treatment of those forms of acute suppurative salpingitis which give rise to the signs and symptoms of pelvic peritonitis. It is not intended to refer to so-called catarrhal salpingitis, which does not pronounce itself by the signs of definite peritonitis and never requires more than the simplest medical treatment for its relief.

## Clinical Definition of Acute Suppurative Salpingitis.

Before discussing the treatment of the disease in detail it is necessary to define its clinical manifestations. It is essentially an attack of acute suppurative pelvic peritonitis with a background of genital symptoms due to acute suppurative salpingitis. Thus we find that a patient suffering from acute salpingitis has acute pain, tenderness, and rigidity of the hypogastrium, with the ordinary accompaniments of moderate fever. A little later there is distension of the lower abdomen with constipation, sometimes vomiting, and painful micturition. In addition there are uterine haemorrhage, leucorrhoea, and great tenderness by vaginal examination. No definite swelling can be identified during the first few days on account of the softness of the enlarged tube and the pain of examination. It is essential, however, to diagnose the presence of free pus in the pelvic cavity during these earliest days before a definite tubal swelling has had time to form.

## The Aim of Treatment.

The cardinal lesions requiring treatment are: (a) suppurative inflammation of the tubes, and later the ovaries; are inseparable and cannot be regarded independently. The first object, therefore, of any intelligent treatment must be to arrest the acute disease and prevent its extension to the abdominal cavity proper. It is seldom that a general peritonitis arises as a result of acute salpingitis except after full-term labour, when the tube is an abdominal organ; but if the disease is treated efficiently it is possible to cut short the long-drawn-out course of tubal and pelvic suppuration which occurs when treated by expectant methods.

The second object is to prevent the formation of chronic sequelae in the shape of adhesive pelvic peritonitis, interstitial salpingitis, pyosalpinx, etc. Too little attention is paid to this aspect of the disease. It is virtually impossible for a suppurative salpingo-peritonitis to resolve unless operated upon. Chronic thickening, adhesions, and cold abscesses are the almost inevitable result, producing a chronic semi-invalidity with relapses of acute symptoms. Furthermore, a bilateral salpingitis is certainly followed by sterility.

The third object of treatment is to enable the affected tube to resolve sufficiently to resume its normal function. Suppurative salpingitis, by its denudation of epithelium and formation of intratubal adhesions, in addition to sealing of the abdominal ostium and fixation by intratubal adhesions, ensures the future sterility of the patient, which is a serious matter for a young married woman affected by gonorrhoeal salpingitis soon after marriage. It

The employment of expectant and medical methods will usually result in the acute symptoms passing off and the subsidence of any inflammatory mass in the pelvis. The patient "recovers" and is able to get up in about three weeks and resume her ordinary occupations; but she is inevitably sterile thereafter, and the slow development of chronic salpingo-oophoritis or pyosalpinx is only a matter of time. If acute suppurative salpingitis is capable of resolution as a result of medical treatment, how does the most operation on the tube is for these chronic forms of inflammation. The great frequency of this disease and of operations for its cure after years of pain, menorrhagia, and sterility, is an indication of the ordinary sequel of the disease in the acute form. It would appear, therefore, that medical methods, although they may suffice to nurse the patient through the acute stages into a convalescence, are insufficient as treatment, in so far as the patient is left with a chronic inflammatory pelvic focus and all its symptoms. It is obvious that something more is necessary. Complete treatment can only be accomplished by surgical means—that is to say, by laparotomy—and proper treatment of the tube.

The ideal is to arrest the destructive inflammatory process at the earliest possible moment. As we have seen, the desquamation of the tubal epithelium and the formation of the intratubal adhesions and diverticula and the sealing of the ostium comprise the essential damage from the process begun very early in the disease. The chief element in the tube is its clitic epithelium, for on its integrity depends the function.

It is important, therefore, to operate as soon as possible—in other words, as soon as the disease is diagnosed as a suppurative salpingitis. The sooner the appendix is opened the easier is it to restore tubal function by arresting the destructive suppurative process.

The chief objections to operation during the acute stage are (1) that it is usually "unnecessary"; (2) that it may be dangerous in spreading infection. We have already discussed the first objection by suggesting that though medical treatment may succeed in assisting the patient through her acute stage, yet surgery is necessary for the prevention of chronic tubal disease. The second objection used to be urged against operation for acute appendicitis before the fifth day. It is no more valid as applied to salpingitis than to appendicitis, probably less so, as the organisms of acute salpingitis are usually of a less virulent order. It is stated that laparotomy in the acute stage is dangerous inasmuch as it is liable to spread infection into the general abdominal cavity. By an ordinarily careful technique the abdominal no more likely than in acute appendicitis.

During the last three years I have been able to trace eleven cases of acute suppurative salpingitis operated on within a few days of the first onset of pain. There have been no deaths, and all the cases have done well. I have excluded dangerous diseases, and is anatomically and pathologically different from the non-pneural variety.

From the arguments set forth, contending that medical treatment is very liable to be followed by chronic disease and that the risk of the operation is extremely small, the case for surgical interference appears to be established. Further, our knowledge of the pathological processes going on within the tube serves to indicate that such surgical treatment should be as early as possible.

## The Operation.

The abdomen having been opened and the abdominal cavity proper carefully packed off from the pelvic cavity, the tubes are inspected to note their condition. In all true cases of the suppurative disease in the acute phase the tubes are greatly congested and plum-coloured, with oedematous

the lecturers and makes all the necessary arrangements. All inquiries should be addressed to the Director of Post-Graduate Studies, Pathological Department, Bristol University.

#### *Daily Post-Graduate Study.*

For those who are able to devote several hours each day to hospital practice the university offers special facilities for post-graduate work. Qualified medical practitioners may be appointed as clinical assistants for a period of one or more months. They may act as assistants, if times permit, in more than one department and in any of the hospitals during their period of study. They will be entitled to the use of the clinical laboratories and medical library, and have the right to attend in all departments, including operations, post-graduate and ordinary clinical demonstrations, and post-mortem examinations. Fee, £3 3s. a month.

#### *Post-Graduate Clinical Work.*

Demonstration courses with weekly lectures are held during May, June, and July. Fee, £2 2s. All inquiries and applications for admission should be addressed to the Director of Post-Graduate Studies (Clinical Section), Pathological Department, University of Bristol, who can be seen on any day by appointment at the Pathological Department.

#### WEST LONDON POST-GRADUATE COLLEGE.

The work of this institution is carried on at the West London Hospital, the first in London to devote its clinical material solely to the instruction of qualified medical men. The college started in 1895; it is provided with lecture, reading, writing, and class rooms, and accommodation of all sorts for the convenience of post-graduate students. In the five years before the war the yearly entry averaged over 220. The work of the college is eminently suitable for men who wish to revive their general clinical knowledge after war work.

As for ward work, the students accompany the senior staff on their visits to the wards at 2.30 p.m. daily, and also go round with the resident medical officers in the morning. Out-patient work begins at 2 p.m. This department is large, and affords ample facilities for post-graduates to see and examine patients. There are the usual special departments. Post-graduates are appointed to act as clinical assistants for three or six months. There is no charge to members of the college. Special practical classes are held in medicine, general practical surgery, gastro-intestinal surgery, medical and surgical diseases of children, analysis of blood and urine, cystoscopy, venereal disease, tropical diseases, retinoscopy, ophthalmic operative surgery, and, when material is available, in operative surgery. The size of the classes is limited. A special clinic for the treatment of venereal diseases (male and female) is held every evening (Saturdays included) at 5.30. Graduates are admitted to the work of the clinic free, and certificates of satisfactory attendance and work are given.

Operations take place at 2 p.m. daily, the surgeons often availing themselves of the assistance of the post-graduates, and in any case making arrangements so that they can readily see what is going on. The anaesthetists give instruction in the administration of anaesthetics, including spinal analgesia, on the operating days, students being allowed to administer them under supervision, while special classes are held in each session. The pathological laboratory is in charge of a pathologist who attends every day.

Demonstrations are ordinarily given in the morning by the assistant physicians and surgeons, and by the medical and surgical registrars.

*Fees.*—Hospital practice, including all ordinary demonstrations and lectures, £1 11s. 6d. for one week, £4 4s. for one month, £6 6s. for six weeks, £9 9s. for three months, £15 15s. for six months, £23 12s. 6d. for one year, and £45 for a life ticket. Instruction in the administration of anaesthetics is given at the rate of £3 3s. a month.

The certificates of the school are recognized by the Admiralty, the War Office, the Colonial Office, the India Office, and the University of London (for higher degrees). A prospectus can be obtained on application to the Dean.

#### NORTH-EAST LONDON POST-GRADUATE COLLEGE.

The headquarters of this post-graduate school are situated at the Prince of Wales's General Hospital, in the midst of a densely populated North London district. It contains 125 beds, and is within a few minutes' walk of South Tottenham Station on the Midland Railway, Seven Sisters Station on the Great Eastern Railway, and Tottenham Hale on the Great Eastern main line. It is readily accessible by electric tram from Finsbury Park and Hackney, and from Dalston, Edmonston, and other parts of North London.

The college is recognized by the Admiralty and the India Office for the purposes of study leave, and by the University of London as a place for advanced study for the M.D. and M.S. degrees; the course of practical teaching of bacteriology is approved by the University of Cambridge for its D.P.H. diploma, and there are ample arrangements for the convenience of men who are thus working, or who, being in active practice, are desirous of getting themselves into touch with modern methods. The hospital as a whole affords excellent facilities to qualified medical practitioners who wish to take part for a time in the work of an active general hospital, or to obtain special instruction in the several branches of medicine and surgery, since it is open to them to study diseases of the eye, ear, throat, nose, skin, fevers, children's diseases, psychological medicine, dental surgery, radiography, the application of electricity in disease, and the administration of anaesthetics. Throughout the sessions into which the year's work is divided, clinics, lectures, and demonstrations are given by members of the teaching staff in the lecture room. Operations are performed every afternoon of the week except Saturday. Special classes are arranged in modern methods of the investigations and treatment of disease, and special intensive courses are held at intervals throughout the year, each lasting two weeks, clinical instruction being arranged for each hour of each day.

*Fees.*—Two guineas for a three months' course of study in any one department, which may be begun at any time; a fee of 5 guineas admits to the whole practice of the hospital for a similar term (one month, 2 guineas, and one year, 10 guineas); and a perpetual ticket for the practice of the hospital may be obtained for 15 guineas.

Additional information can be obtained from the Dean of the Post-Graduate College, at the hospital, or at 39, Harley Street, London, W.1.

#### AUSTRALIAN AND NEW ZEALAND MEDICAL ASSOCIATION.

Some members of the profession born in Australia or New Zealand and now resident in England have formed an Australian and New Zealand Medical Association to give information and advice to medical visitors from the Commonwealth and Dominions with regard especially to attendance at special clinics, post-graduate work, and facilities for preparing for examinations such as the M.R.C.P., F.R.C.S. (England and Edinburgh), and the D.P.H., and also as to house appointments and clinical assistantships in London and the provinces. Information will also be given as to lodgings, sports, and social opportunities. All medical graduates or undergraduates born in Australia or New Zealand and resident or visiting England are eligible to become members. The fee is one payment of 5s. Further information can be obtained from the joint honorary secretaries, Mr. E. T. C. Milligan, F.R.C.S., and Mr. Bedford Russell, F.R.C.S., 86, Harley Street, London, W.1.

#### TROPICAL MEDICINE.

THERE are large and important schools of Tropical Medicine in London and Liverpool, and several universities and other examining bodies have instituted diplomas or degrees in the subject. The Colonial Office now expects all nominees for the Colonial Medical Service to pass through one or other of the two schools mentioned before their appointments are confirmed; and commercial firms engaged in tropical enterprise commonly demand from medical applicants for employment corresponding evidence of special knowledge. Information with regard to these schools and diplomas and degrees follows.

state of affairs not due to salpingitis at all, but to appendicitis, tubal gestation, infection of a pre-existent tumour, etc.—conditions which manifestly should have been treated by immediate operation.

Disparately reviewing the experiences I have related to you I came to the conclusion that the treatment of acute salpingitis is as taught and exemplified to me was all wrong, for the medical treatment was not treatment at all and the surgical treatment had obviously been postponed till too late. I therefore began to operate on every case as early as possible—on the first day if I got the chance.

I had been taught that early operation was dangerous, and if this was true it would be better in many cases not to operate at all—the very bankruptcy of surgery. But it is not true. This is a most important point and must be settled at this outset.

I have operated on a large number of cases of early salpingitis during the last twenty years, and the only case I have lost died of delayed chloroform poisoning. These operations of early operation who maintain that it is dangerous speak without experience. I asked one of them who was thus denouncing the practice whether he had ever operated on an early case. He replied, "No; I consider it criminal." Now, had he told me that he so operated but had given it up on account of his bad results I should have been impressed, but as it was I merely noted another example of good natural mind, hopefully tethered, tied, and bound in the net spread by his teachers.

It has been suggested that patients operated on early have frequently to be repaid on account of collections made frequently by the patients' recovery must be adopted, irrespective of what happens to the tubes. Evidence as to the subsequent value of tubes that have been inflamed is badly wanted, and I hope that this discussion will result in a certain amount of such evidence becoming available. It is no use reciting the case of Mrs. Brown, who was treated non-operatively for salpingitis five years ago and now is six months pregnant, for there is no certainty that both Mrs. Brown's tubes were inflamed. What we want is a record of cases where the abdomen was opened, both tubes were found inflamed, one or both were conserved, and the patient subsequently conceived, and at present early operation with conservation of the tubes has not been practised sufficiently long for any considerable number of such cases in the practice of one surgeon to become available for evidence. For this reason single cases of that kind should be published at once so that we may the quicker obtain the desired body of evidence.

While not denying that an inflamed tube may recover so entirely as to allow of pregnancy occurring, I am at present of opinion that such recovery is rare. This opinion is founded on pathological and clinical considerations, and my experience of abdominal section on patients who years before had had salpingitis. Of direct evidence I have only one case, and that not conclusive. I operated on a patient with only one tube and that inflamed (the other had been previously removed), and I conserved the tube. A year or two afterwards I reopened her on account of an inflammatory ovarian cyst, and found the tube apparently recovered, though I did not inflate it. She had not conceived, though living with her husband, but, on the other hand, her one and only ovary was cystic.

Since it has been my practice until the last few years always to remove the early inflamed tubes, I cannot draw evidence in this connection. The number of cases in which I have conserved the tubes and drained is relatively small, and still smaller are those in which I have slit the tube.

My experience of conservation with drainage has not

been particularly encouraging. All my cases recovered, but one very nearly died of paralytic ileus, and none of them have conceived since the operation, so far as I know. Twice I have subsequently had to reoperate on account of chronic discases of the appendages.

The operation of sitting, I must say, appeals to me as being much more likely to lead to complete restoration of the tubal function, but one must remember that though it makes future closing of the abdominal incision less likely it can have but little effect on closure towards the other end of the tube, and this is really the more serious of the two events. Should the evidence, when sufficient is accumulated, show that complete recovery of an inflamed tube is not uncommon, then the actually inflamed tube must be conserved whenever possible. Conservation may be practised by (1) not operating at all, or (2) conservative operation, either by simple drainage of the pelvis or by sitting and drainage. Since it is very rare in delayed operations to find the tubes in a condition suitable for conservation, the choice would be between not operating at all and early operation with simple drainage or sitting and drainage. Of the two I have not the slightest hesitation in deciding for early operation. Early operation, as I have stated, is exceedingly safe when the tubes are removed, and evidence seems to show that the risk is at all events not greatly increased by conserving the tubes.

Early operation has the great advantage over expectant treatment that the ovaries can always be conserved, whereas by withholding the surgeon's hand, though a proportion of the patients eventually recover their health, in the remainder the ovaries become hopelessly disorganized by suppurative or cyst formation, and eventually the unfortunate woman has to undergo double salpingo-oophorectomy. These delayed operations are, as I have said, at all times serious, and often most formidable and difficult, and I never perform one myself or watch one being performed without regretfully remembering that had the disease been attacked surgically at its incidence a very simple and safe operation would have sufficed to cure the patient.

A pyosalpinx or an ovarian abscess is, in my opinion, a disastrous to the surgeon if the delay which allowed of such forming can be laid to his door. The parallel with appendicitis is a fair one. There the surgeon seeks to operate before abscess formation because the operation is safer than after an abscess has formed. In salpingitis, also, the operation is safer before abscess formation, but in salpingitis there is additional reason for early operation. No one wants to conserve an appendicitis, healthy or unhealthy; but the ovaries is a different matter, and now evidence is accumulating that the tubes may be saved if operated on early enough. Natural cure of a pyosalpinx or an ovarian or pelvic abscess is usually effected by adhesion to the pelvic colon with discharge of the pus into the bowel. Relief, however, is not immediate as a rule, and, moreover, the abscess cavity at more collections of pus, and, therefore, there are generally two or three abscesses analogous to a blind intestinal fistula with fecal infection of its wall and contents, so that prolonged suppuration with intermittent discharges of pus per anum is not uncommon. In delayed operations the surgeon frequently has to dislodge a tube or ovary which has already perforated or is on the point of perforating into the bowel, with the result that a faecal fistula up the drainage track develops within the first few days. This is another important objection to delayed operation and a valid reason in favour of surgical interference at the earliest possible moment. Finally, as a reason for immediate operation, there is always the possibility of faulty diagnosis. These are cases of pelvic appendicitis, diverticulitis, and also early extrauterine gestation, which it is impossible at the outset to distinguish from salpingitis.

But supposing that the evidence—when sufficient is accumulated—shows that inflamed tubes very rarely remain intact, how shall we stand then? A few years ago my answer would have been simple: The tubes, being practically valueless, need not be considered and should be removed as early as possible, since by early operation we save the ovaries from secondary infection and the patient

facilities for the study of psychological medicine in the general hospitals are now much greater than in former years. Thus many of the teaching hospitals have out-patient departments for the treatment of mental cases, and in some of these hospitals special lectures are given on psychopathology. These facilities need not be utilized by the student, however, and the compulsory part of the curriculum is confined to formal lectures and a few attendances at some mental hospital. Here the student is apt to see mainly the terminal states of mental disease, and he is also apt to gain the impression that mental disorder is necessarily related to segregation and custody. We would therefore impress upon him the importance of attending the out-patient department for mental disorders where he will be able to observe the mild and early cases such as he will hereafter meet with in general practice.

The Ministry of Health has recently issued a memorandum by Sir George Newman on *Recent Advances in Medical Education in England*.<sup>1</sup> The inadequacy of the facilities for the teaching of psychopathology is there commented upon, and it is pointed out that the general practitioner must be competent to diagnose all the chief forms of mental disease and defect (Lunacy Act, 1890, Mental Deficiency Act, 1913, Elementary Education (Defective and Epileptic Children) Acts, 1899 and 1914). The certificates under these Acts are shown to necessitate a diagnosis, a record of the clinical grounds for it, and in some cases the medical reasons for detention or custodial care. It is evident, as Sir George Newman points out, that these requirements are sufficiently exacting to render necessary the proper education in this subject of every medical student; and it should be practical and the subject of examination. The curriculum in mental diseases suggested is as follows:

"(i) A short course of lectures in normal psychology, preferably as part of the course in physiology (reflexes, habit, instinct, emotion, intelligence, the conscious and the unconscious mind, Binet tests, investigational methods, etc.).

"(ii) Half a dozen explanatory discourses in abnormal psychology, to be taken concurrently with clinical work in mental disease.

"(iii) Ten or twelve systematic lectures on mental disease, concurrently with clinical work, and clinical demonstration, at a mental hospital of in-patients, pronounced cases (recent or chronic), and the usual types of insanity.

"(iv) A series of demonstrations in the out-patient clinic for nervous and mental disorders at the general hospital.

"What the student needs is instruction in the etiology, symptoms, diagnosis, treatment, and prognosis of the morbid mental states most commonly met in general practice. The student must also be trained in case-taking, the examination of patients dealing with relatives of patients, certification, precautions, etc."

A scheme is now in actual operation at the Middlesex Hospital in which a small number of mental cases are treated in the hospital as in-patients. This is an important move from the teaching point of view, because the student will gain true insight into the relation between mental disorder and medicine as a whole, and he will realize that it is a form of illness to be studied with other diseases and to be treated along similar lines.

In London post-graduate courses of instruction of a comprehensive kind are given at the Maudsley Hospital and at Bethlem Hospital; and at the National Hospital for the Paralyzed and Epileptic, Queen Square, courses are arranged to meet the requirements for the diploma in psychological medicine in regard to nervous diseases. Courses in mental deficiency are arranged by the University of London. There are also post-graduate courses at the Universities of Edinburgh, Glasgow, Cambridge, Birmingham, Leeds, Manchester, Durham, and elsewhere. Those who are taking up psychiatry as a career will find it desirable to obtain a diploma in psychological medicine. Such a diploma is not at present compulsory for a permanent position on the staff of a mental hospital, but it will probably become so in course of time, just as it is now essential to obtain the D.P.H. if a career in public health is contemplated. Psychiatry is one of the branches of medicine which candidates for the M.D. degree of the Universities of London and Edinburgh can take up, and, in addition,

diplomas in psychological medicine, to which reference has been made, can be obtained from the Universities of Cambridge, London, Edinburgh, Durham, Leeds, Manchester, and the National University of Ireland, and from the Conjoint Board in England. The Medico-Psychological Association of Great Britain and Ireland also grants certificates of proficiency after examination and encourages the study of psychiatry by the offer of prizes for original and research work.

#### Mental Hospital Appointments.

Those who take up psychiatry as a career work as medical officers of public or private mental hospitals or similar institutions. Except in the larger institutions, such as those under the control of the London County Council, where a number of the medical officers are allowed to live out if married, the medical staff are resident officers, having board, lodging, etc., either in the hospital itself or a residence in the grounds. Junior assistant medical officers receive about £300 to £400 per annum, and senior assistant medical officers about £500 to £700, in both cases with board, lodging, laundry, etc., in addition; if married, the board, etc., is commuted for cash. As the mental hospitals are under local control the salaries vary much in different asylums. Medical superintendents, whose pay commonly ranges between £800 and £1,500 per annum, are provided with a house in the grounds of the hospital and draw various allowances.

Since the passing of the Asylum Officers' Superannuation Act in 1909, all officers and others of the established staff of a public (county or borough asylum) mental hospital may retire at the age of 55 on a pension varying from one-half to two-thirds of the value of their pay and emoluments, or one-fiftieth for every year served, paying as contribution 3 per cent. of the value of their appointments annually. This very favourable prospect may not appeal to junior practitioners joining the services, but will eventually prove to be a valuable asset.

#### Prospects in the Public Service.

Appointments to the public mental hospitals are made by the Visiting Committees, and in most cases only the junior posts are open to those who have not had previous experience in psychiatry. Since the public mental hospital service is a local and, except indirectly, not an imperial one, the promotion tends to be slow and uncertain, and the higher positions are not always advertised and thus thrown open to competition. For this and other reasons mental hospital work has undoubtedly not been in favour with newly qualified men in years past, but the general conditions of service have tended to show a progressive improvement and will in all probability continue to do so in the future.

In March, 1920, the Board of Control did useful service by issuing to visiting committees of asylums a circular upon the three following matters: (a) the dearth of suitable applicants when vacancies occur for the post of assistant medical officer, and the probable causes thereof; (b) the need of provision for the more effective treatment upon modern lines of recoverable cases of mental disorder; (c) the necessity for raising the standard as to the training of existing and future assistant medical officers in asylum practice, and of affording facilities for such training.

Under (a) the Board of Control, after pointing out some of the disadvantages of the present state of affairs, made the following suggestions:

(i) That an improvement be made in the salaries of the assistant medical officers, at least to such an extent that in the cases of all those who have been in the service above a certain number of years and are regarded as permanent officials, the salary should be reasonably sufficient for a married medical man, and that in the case of the deputy superintendent it should more closely approximate than at present to that of the superintendent.

(ii) That, in the case of a permanent official, application for permission to marry be not required; that, according to circumstances, proper accommodation for a married man be provided, and that subject to rules approved by the Secretary of State for the protection of the patients, and with due regard to the proper administration of the institution, permission to live out may be granted.

(iii) That to the title of assistant medical officer the words "and deputy superintendent" should be added to that of the one selected to be in charge during the absence of the medical superintendent.

(iv) That the use of the title "senior assistant medical officer" should not be restricted as at present to the post of first assistant, but should be extended and be indicative of a certain standing and

<sup>1</sup> H.M. Stationery Office, 1923. To be purchased through any bookseller. 1s. 3d. net.

so far 5 of these have become pregnant—that is, 25 per cent. Most of these cases presented few or no physical signs, and their chief complaint was sterility. It is only a small series, but some interesting facts emerge from a closer study.

*Choice of Cases.*

In choosing cases for operation the following factors were taken into consideration as suggesting the likelihood of tubal occlusion or obstruction following salpingitis:

1. The failure of other methods of treating the sterility, including dilation, alone or with insertion of a stem, incision of the cervix, or curettage. Most of the patients in this series had already been subjected to one of these operations without conception resulting.
2. The occurrence of an early miscarriage followed by sterility lasting more than eighteen months, especially if uterine operations, such as curettage, were without effect after the miscarriage.
3. The occurrence of a definite gonococcal cervicitis in the past. Some of the cases had been treated for gonococcal cervicitis, proved by positive cultures, and some gave a history of suffering an attack of salpingo-oophoritis in the past. A history of past attacks of appendicitis is also not without significance.
4. In some of the cases there was present an unsuppressed cervix with an issuing chronic mucopurulent discharge, which though giving negative cultures was associated with a history of gonorrhea in the husband.
5. In about half the cases dyspareunia was associated with definite tenderness in one or both fornices. This is a significant and valuable sign in cases where no lesion of the tubes is palpable on bimanual examination.

*Details of Findings.*

The following conditions were found:

1. Tubes of almost normal length and thickness, mobile, slightly convoluted, and with normal lustre, but with closed and club-like ostial ends, occasionally showing a central dimple. On opening the tubes a little clear sterile fluid can usually be expressed. The club-ended tubes are almost invariably the result of gonococcal infection, and usually bilateral, free from adhesions, and when the ambral and is reopened can be easily probed to the uterine extremity. Even under anesthesia, before the abdomen is opened, it is impossible as a rule to detect any abnormality in the pelves in these cases.
2. Tubes of normal length and thickness, but adherent to the ambral ends and along their lateral aspects to the back of the broad ligament or the sides and floor of the pelves. These cases are usually the result of streptococcal or mixed infection following abortions, and intrauterine operations, especially stem insertions of more than forty-eight hours' duration. Occasionally in these cases there are so many adhesions that the pelves is roofed over and it is impossible to reach the tubes and ovaries without risk of damaging to the intestines or the lighting up of a dangerous streptococcal infection. Moreover, unlike the mobile closed gonococcal tubes they are frequently adherent to the ovary and at the ostial ends, a false fibrous capsule of condensed lymph covering both the ovary and the end of the tube in such a way as not only to occlude the tube but also to render ovulation impossible. In such cases the ovary can be shelled out of its fibrous bed quite easily, and given a new lease of procreant life.
3. Tubes open at the ostial ends but kinked, stenosed, or obstructed at one or more points, so that the tube cannot be threaded throughout its entire length over a fine probe or blunt-ended needle. This is most often occurs at the point where the tube curves backwards and inwards towards the middle line almost midway between osium and uterus. They are usually the result of mild mixed infections, not sufficiently severe or prolonged to close the tubes, but serious enough to produce a local stenosis and fibrosis at the point where narrowing of the bent canal usually occurs.
4. Tuberculous affections of the tubes occurred in 5 of the 25 cases, or 20 per cent.
5. A most striking feature in this series was the clinical pancy of physical signs in association with bilateral pathologic lesions of the tubes and ovaries sufficiently serious to produce sterility.

*Operative Technique.*

The following reconstructive operations on the tubes were performed: (a) salpingostomy; (b) partial salpingectomy; (c) resection and anastomosis; (d) incision and re-suture after canalization.

1. After puncturing the club end of the tube the incision is dilated with a forced into the tube by a metal ear syringe; any kinks or stenoses are thus exposed.

2. After the patency of the incision has been tested by threading the tube over a fine blunt-ended needle, the dorsal surface of the ostial end is slit over a fine blunt-ended needle, so as to leave an everted mucous membrane and a buttonhole stich. A strand of No. 4 catgut can be left in the lumen.

very fine needles, using a continuous buttonhole stich, taking care to evert the mucous membrane and not to puncture up the new opening, but to secure arrest of bleeding from the oversewn edges. (See Diagram I, No. 2.) Then one or more strands of No. 4 catgut can be passed for a short distance into the tube lumen, threaded on a needle, the latter being pushed inwards, blunt end first, so as to release the catgut and leave it in the tube lumen. The other end can be left free or given a point d'appui by running it through the edge of the ovary or adjacent broad ligament.

Finally, when both tubes have been reconstructed the round ligaments, and if necessary the ovarian ligaments, are shortened, leaving tubes and ovaries suspended from the back of the broad ligament in a position less favourable to the development of adhesions. After cannelizing the second tube, 1/2 per cent. violet-green can be syringed through, so that the patency of both canals can be demonstrated by the orange and violet on the cervical swab. On one occasion the following slight modification was made. After sitting up the dorsal aspect of the ostial end of one tube for 1 1/2 inches, the free edge was sewn to the side of a piece of ovary was partially detached and left in situ, so as to enclose a ripening follicle. On the other side a piece of ovary was partially detached and left in situ, so as to enclose a ripening follicle. This patient has not yet reported herself to be pregnant. It is not necessary to drain cases of gonococcal origin, but streptococcal cases, especially if many adhesions have been separated, are best drained for twenty-four or forty-eight hours by a strip of iodiform gauze running from the bottom of Douglas's pouch into the vagina.

## PUBLIC HEALTH SERVICES.

## GENERAL CONSIDERATIONS.

THE Public Health Service, to use the term in a strict sense, consists of medical officers of health appointed by local public health authorities and holding office under varying conditions of tenure. In addition there are county medical officers appointed by the county councils. The latter are not, strictly speaking, public health authorities; the duties of their medical officers are somewhat similar to those of other medical officers of health, but, in England, include few executive functions. In many of the county boroughs and counties assistant medical officers of health or assistant county medical officers are appointed, and such appointments may afford stepping-stones for promotion to higher offices. The service is, however, not unified throughout the country, and there is no regular system of promotion; appointments are to be obtained only by application to some particular local authority which has advertised a vacancy.

Three other services also ungraded have been brought into existence by recent legislation; their members are charged with duties which bring them into more or less direct relation with public health authorities or county councils and their officers. They are school medical officers, tuberculosis officers, and venereal disease medical officers. Appointments as school medical officer are made by local education authorities, while appointments as tuberculosis officer and venereal disease officer are made by the county councils and the county borough councils.

The medical department of the Ministry of Health for England has been organized under the control of a chief medical officer who has the status of an assistant secretary: it contains six sections, with a senior medical officer at the head of each. These sections are concerned with general health and epidemiology, maternity and child welfare, tuberculosis and venereal disease, the supervision of food supplies, and sanitary administration in relation to infectious disease. There is a separate section concerned with insurance practitioners. Lastly, there are medical officers employed in the Poor Law department and several whose services are available for special purposes but who are not "established" officers. Medical officers and medical inspectors are also employed by the Ministry or the corresponding Board in Wales and in Scotland. Appointments to these posts are not open to public competition; they are made by the Minister of Health in England and Wales and by the corresponding head of the department in Scotland. They are civil service appointments, and come under the superannuation scheme of the service.

MEDICAL OFFICERS OF HEALTH IN ENGLAND  
AND WALES.

The first appointments of medical officers of health were made for limited periods, the holder of the office having to risk re-election at the expiration of his term of office. This pernicious practice, so far as it applies to whole-time officers, owing to the persistent endeavours of the British Medical Association, in co-operation with some other bodies, ceased to exist after April 1st, 1922; as regards medical officers of health appointed prior to May 1st, 1921; it is not in operation as regards those appointed after the latter date. The Public Health (Officers) Act, 1921, which was promoted by the British Medical Association, provides that a whole-time medical officer of health shall not be appointed for a limited period, and shall not be removed from his office except with the consent of the Minister of Health. This Act came into operation on April 1st, 1922, but an order of the Minister of Health dated April 12th, 1921, makes a similar provision with respect to those officers appointed after May 1st, 1921.

A medical officer of health who does not devote his whole time to the duties of his office, and a portion of whose salary is obtained from Exchequer grants, may be appointed without limit of time, in which case he cannot be removed from office without the consent of the Minister of Health. If he is appointed for a specified term, say one year, he continues to hold office from year to year unless the Minister consents to his removal or the electing authority gives him three months' notice to resign his office, but the notice must take effect at the same period of the year as that at which the original term

of appointment expired. Where the electing body pays the whole of the salary of a medical officer of health he may be dismissed from office without reference to the Minister of Health.

An increasing number of local authorities have established schemes for the superannuation of their officials, but there is no general scheme throughout the country. During the past twenty years the British Medical Association has on several occasions succeeded in getting introduced into Parliament a bill providing for the superannuation of medical officers of health, but the measure has always been opposed by the Government of the day, latterly on the ground that all municipal officers should be superannuated, and that sectional legislation was undesirable. In this connexion it may be stated in passing that medical officers of health are the only State-paid (whole-time) medical officers who do not come under a superannuation scheme.

A medical officer of health of a county or of a district or combination of districts with a population of more than 50,000 persons must hold a diploma in public health. This diploma is now generally required from all applicants for whole-time appointments of medical officers of health and assistant medical officers of health, and very frequently in the case of school medical officers, tuberculosis officers, and venereal disease officers. A medical man who desires to enter the public health service as a career must as a first step obtain such a diploma.

## Position in Scotland.

The above statement applies specially to England. In Scotland the position is different in several respects. The central authority is a Board of Health which has at present four members, with offices in Edinburgh. One of the four is a medical man. It is now proposed to reduce the membership to three as existing appointments expire, and to abolish the qualifications of future members, so that not one of the three need be medical.\* The "Board" system is the rule in central government north of the Tweed, there being also Boards of Agriculture, Fisheries, Education, and Control (of lunatics). The Secretary for Scotland, whose chief office is in Whitehall, is over all, and there is a Parliamentary Secretary. Both of these are members of the Board, the Secretary for Scotland being President, and one of the Edinburgh members Vice-President. The Board has a staff of medical officers and of referees for insurance work. Under the Public Health (Scotland) Act, 1897, no one can be appointed as medical officer of health for any area, burghal or rural, however small, unless he possesses a diploma in public health. One result is that small burghs often appoint the county M.O.H. as their officer. No medical officer or sanitary inspector can be removed from office except with the sanction of the Board of Health. A "proper" salary must be paid, and it is incompetent for the local authority to bring about a resignation by indirect means, such as reducing a salary, or attaching conditions to the appointment. The Act says nothing about superannuation, and specifies no retiring age. The appointment, however, is not *ad vitam aut culpam*. Most counties in Scotland are smaller than in England, and the county medical officer is also district medical officer, being therefore both administrative and executive in function. A few counties are not divided into districts.

## THE SCHOOL MEDICAL SERVICE.

School medical officers are appointed by local education authorities under schemes of medical inspection of school children which must be approved by the Board of Education. Primarily their duty is to detect among the children attending the public elementary schools any physical or mental defect which may retard the education of such children, and to inform their parents of its existence. But practically their duties vary considerably in different areas. This is because most approved schemes of inspection include systems of work which aim at facilitating the task of parents in obtaining for their children the necessary treatment, at checking the results of the latter, and at keeping each defective child under skilled observation both at home and at school until it has passed altogether out of the education authority's hands. The general object of all schemes alike is to make

\* See BRITISH MEDICAL JOURNAL, August 18th, 1923, p. 293.

cases. Except in one case no operation was performed more than two years ago. Three successes were in cases of bilateral salpingostomy, for closed club-ended tubes—one a case of bilateral resection and anastomosis, and one in a case of bilateral incision and suture after separation of adhesions with resection of one ovary. No successes have followed in cases of partial salpingectomy and in operations performed at the uterine end of the tube.

*Laparotomy in Sterility. The Place of the Operation.*—Are we justified in advising laparotomy in cases such as these, where the only complaint is sterility? It is a question upon which diverse opinions are held. Against the operation it can be argued:

1. That all abdominal operations are a risk to life. No matter how capable the surgeon, he is extremely fortunate if he is able to perform 100 operations without mortality, for a lunimortality embolism, which we are as yet unable to prevent, occurs in 1 per cent. of cases.
2. The reopened tubes may close again or adhesions may occlude them.
3. The lining of the tubes may be unhealthy. Though patency may be restored, the inflammatory process which originally sealed them may have destroyed or unfavourably modified the mucous lining with its delicate cilia and necessary secretion.
4. Cases of extrauterine pregnancy have been reported after salpingostomies.
5. It is a tradition of surgery that operations are undertaken to save life or relieve suffering, and as a rule neither justification can be argued in these cases. In other words, not only is the woman incurring a risk, both immediate and remote, but fertility cannot be promised as a result of the operation.

On the other hand it is only fair to remember:

1. That while such an operation is not performed to save life or as a rule to relieve suffering, it may actually be the means of creating a new life; and that when symptoms such as pain are present they are frequently relieved by the operation.
2. The successful cases are surgical triumphs in which intra-uterine operations, so often repeated and varied, are doomed to failure.
3. Fertility cannot be promised, neither can it be ensured, by any other method of treatment, but laparotomy does at least allow inspection of the tubes and ovaries, and possibly correction of the bar to fertility. When the abdomen is closed it is at least established that everything possible has been done to favour pregnancy, and probably the chances have been improved. It is a question of balancing the risks of operation against the improved chances of conception. The correct attitude is to explain this to the patient, to show her both sides of the picture and let her decide, an attitude adopted in all the cases in this series. To some women a child means little, to others it means so much, and such women will sometimes ask for operation knowing all its risks and even against advice, if they are satisfied that it improves their chances of conception and ensures that everything possible has been done.

DISCUSSION.

Dr. CURTIS OGDEN (Leeds) said that everyone must have been interested in Mr. Bourne's paper. He personally was much attracted by his suggestions; they were idealistic, aiming not only at the saving of life, but the complete restoration of the patients' functions. He personally did not regard delayed operation on the tubes as very dangerous, but seemed to him that in urging early operation the important question was, Could a case of pregnancy following upon operation be produced? Mr. Bourne could not show a case, in which one definitely inflamed tube had been left behind; there was not a single case of pregnancy in the lot. In another series of thirty cases, where simple posterior colpotomy had been performed, there was one case where subsequent pregnancy occurred; but, of course, in these cases the condition of the tubes was not known. Thus, in forty-seven cases there was only one subsequent pregnancy. He saw very few cases of salpingitis before the operation, in which at operation he had performed salpingostomy on account of excessive loss and sterility, in which at operation he had found a great mass of adhesions which bled very freely. This patient two years later had an ectopic pregnancy with pelvic hæmorrhage on the left side, and following that again

she had two healthy living children. His conclusions were that he would try Mr. Bourne's operation, but he was not very hopeful of the results. He thought they would rarely see their cases as early as the stage described in the paper. He was not entirely convinced of the safety of operation in the acute stage. He did not think that they could justly claim that sitting up the tubes would secure resolution. Drainage by tube would itself probably leave severe adhesions. Again, a certain number of patients leave ectopic pregnancies, more, probably, than would do so if the cases were left alone. The one advantage he could see of early operation was that an inflamed appendix might occasionally be found to be causing all the trouble. Possibly, too, if only one tube were diseased early operation might prevent the other tube becoming involved. His experience of the later cases was that, except in tuberculous cases, facial fistulae were very rare. Certainly most patients got operation, but he was not at all sanguine as to the results.

Dr. JOHN CHAPPEL (Belfast) said that he was the more gratified at the views put forward because when he opened the discussion on this subject at the Annual Meeting in Glasgow last year and advocated early operation, he had received little or no sympathy or support. He was in complete agreement with Mr. Bourne when he insisted on the advantages of early operation. There could be little doubt as to the desirability of saving patients from the prolonged ill health which usually followed the expectant method of treatment. Hence the need for early operation. While he agreed with Mr. Bourne as to the general principle of early operation, he was not able to follow him in his method of operation. He had hitherto removed the bulk of the diseased tube and made a new abdominal mouth for it, using no drainage but filling the pelvis with saline solution. He knew of no case in which both tubes had been operated on in which subsequent pregnancy had occurred. Mr. Bourne had divided his cases into two classes: (1) Those in which the tube was not much damaged and in which he slit the tube and drained; (2) those in which the tube was greatly affected that he considered it necessary to remove it. The drainage was the weak point in his method. Drainage was followed by adhesions, and adhesions were surely likely to be a barrier to the ovum reaching the tube and uterus from the ovary. Drainage thus defeated the main object he had in view—namely, the probability of future pregnancy. Slitting the tube would appeal to him if Mr. Bourne could advise them to get rid of drainage. Colpotomy had been advocated as a method of treatment, but in such cases as Mr. Bourne had been discussing it was useless. By that method they could drain an abscess in Douglas's pouch, but they could not adequately deal with the tubes. It had been objected that tubal pregnancy was likely to result after operation. Surely this was not a valid objection, since a tubal pregnancy could hardly occur in a case in which slitting or resection of the tubes had been done. He contended strongly that early operation was desirable. It had been remarked that the surgeon seldom saw the early cases. That was a matter which the education of the profession and the public would remedy. The same difficulty formerly existed in regard to acute appendicitis, and it had now disappeared.

Professor R. J. DONSTON (Belfast) said that he saw very few cases of the nature described. In acute salpingitis with disease of one hollow organ, as in appendicitis, but with disease which involved the whole generative apparatus, in slitting the tube they were only dealing with part of the disease. The bad results following treatment of the tube were not so much due to the damage to the tube alone, but to the general damaged condition of cervix, endometrium, and ovaries. He thought that there was a slight danger to life in operating on acute cases, small though it might be. The slight additional trauma of the operation might be sufficient to turn the scale and set up general septicæmia. There was a real danger, too, that trauma might extend the local spread of infection. Drainage was certain to produce adhesions. If the source of infection could be got rid of he believed that adhesions would disappear, but if all

## THE PUBLIC SERVICES.

THE ARMY, AIR FORCE, AND INDIAN  
MEDICAL SERVICES.

THE Medical Departments of the Royal Navy, of the Army, and the Indian Government normally employed between them before the war some 3,000 medical men, and vacancies in the ranks of these services were filled by offering commissions for competition once or more each year. In the abnormal circumstances arising out of the war and the period immediately following it the usual regulations for recruiting the permanent medical staff of these services were, for the most part, in abeyance. Now that a return has been made to peace establishments we publish somewhat fuller information than we gave during the war period, for the guidance of those junior members of the profession who think of applying for regular commissions in the Royal Air Force Medical Service and the Royal Army Medical Corps. Further details should be sought from the respective medical departments. The usual information regarding the conditions of service, pay, and prospects in the Medical Department of the Royal Navy is omitted for the reasons stated at page 391.

## ARMY MEDICAL SERVICE.

Competitive examinations for commissions into the Royal Army Medical Corps are held twice a year, usually in January and July.

The prospects of the newly qualified medical man taking up the army as a career have been improved by changes that have come into force since the war. The rates of pay and pension are given in the subjoined tables; they compare favourably with those that obtained in 1914.

## Pay and Allowances.

| Lieut.-Colonel after 20 years' service | 1216                     | 1137                       | 1650                        |
| Lieut.-Colonel after 25 years' service | 1262                     | 1183                       | 1850                        |
| Colonel ... ..                         | 1439                     | 1422                       | "According to appointment." |
| Major-General ... ..                   | 2163                     | 2091                       |                             |

Allowances vary slightly from time to time.

**At Home.**—An officer under the rank of lieutenant-colonel holding an appointment as specialist receives 2s. 6d. or 5s. a day according to subject or group of subjects. An officer in charge of a hospital receives charge pay, the daily amount being: in excess of 50 beds, 2s. 6d.; in excess of 150, 5s.; in excess of 300, 7s. 6d.; in excess of 500, 10s. An officer in charge of a medical or surgical division of a general hospital with not less than 300 beds receives *de facto* rates. Senior Medical Officer Royal Arsenal not exceeding 10s. a day. Officer in Command of the Depot R.A.M.C. 5s. daily. Adjutant R.A.M.C. Depot 5s. daily. Adjutant R.A.M.C. (T.A.) 2s. 6d. daily. Professors at the Royal Army Medical College receive £200 a year, and assistant professors £80 a year, in addition to pay and allowance of their rank.

**In India.**—The specialist pay is 50 rupees a month; charge pay is from 60 to 240 rupees a month, according to the size of hospital.

## Retirement.

A lieutenant-general or major-general must retire on attaining the age of 60 years, a colonel at 57, and other officers at 55. A major superseded for promotion retires on the completion of twenty-five years' service, or, if he fails to qualify for promotion, on the completion of twenty years' service. A captain who fails to pass the examination for promotion to major on a second trial must retire at once with any gratuity for which he may be eligible, or, if not, on completing five years' service. A lieutenant who does not qualify for promotion within three and a half years is required to resign. A candidate who has been specially employed in consequence of a national emergency, either as an officer or in a position usually filled by an officer, will be allowed to reckon such service towards retired pay and gratuity. The maximum rates of retired pay are as follows:

|                              |        |
|------------------------------|--------|
| Captain and Subaltern ... .. | £301   |
| Major ... ..                 | £150   |
| Lieutenant-colonel ... ..    | £600   |
| Colonel ... ..               | £800   |
| Major-General ... ..         | £1,000 |
| Lieutenant-General ... ..    | £1,100 |

Voluntary retirement on retired pay is not allowed until after twenty years' service. Earlier retirement on gratuity is allowed as follows:

|                                           |           |
|-------------------------------------------|-----------|
| Major or Captain:                         | Gratuity. |
| After 31 years' commissioned service      | £1,000    |
| " 3 years' service in the rank of major " | £1,800    |
| " 6 years' service in the rank of major " | £2,500    |

## Seconded Service.

An officer may be permitted to accept employment in the Foreign or Colonial Offices; when so seconded he is not eligible for pay or allowances from army funds, but his service continues to reckon towards promotion and, under certain conditions, towards increase of pay, pension, or gratuity. Among the capacities in which R.A.M.C. officers may be employed are:

- (1) The medical service of the Egyptian Army.
- (2) The sanitary service of the Egyptian Government.
- (3) The medical services of the various foreign and colonial Governments.

## Service on the West Coast of Africa.

Officers for service in West Africa are usually taken from a list of volunteers for such service. An officer at present receives, while actually serving in West Africa (which service may include ordinary leave not exceeding sixty-one days in a year, and any time spent at Madeira or the Canary Islands on sick leave), additional pay at the following daily rates: lieutenant-colonel 12s., major 9s., captain 7s. 6d., lieutenant 6s.

The professional work of the corps has received a great impetus through the Directorates of Hygiene and Pathology. Specially selected and trained officers have now been appointed as assistant and deputy assistant directors of hygiene to all commands and garrisons at home and abroad. Junior officers appointed on probation undergo a course of instruction in hygiene at the army school of hygiene, where lectures and demonstrations are given on the methods of sanitation, including entomology, applicable to the various climates and countries, special attention being paid to tropical hygiene.

The Directorate of Pathology offers many attractions to those officers who are desirous of taking up the scientific side of medicine. Officers who show aptitude in this direction are encouraged to continue their scientific studies during the whole course of their service. As junior officers the posts of clinical pathologists to hospitals at home and abroad are available, while, after their first tour of foreign service, they are given the opportunity of qualifying as specialists in bacteriology and pathology at the Royal Army Medical College; having so qualified they become eligible for the appointments of assistant or deputy assistant director of pathology, posts which carry with them specialist pay or temporary promotion.

Appointments to the staff of the Directorate of Hygiene or Pathology at the War Office are open to officers who have served in these scientific branches—the senior posts carrying the rank of colonel or major-general as the case may be. All such staff appointments, either at the War Office or in commands at home, have a fixed tenure of three or four years should the exigencies of the service permit.

Arrangements have been made for the appointment of consultants in both medicine and surgery, and the ranks of colonel and major-general are now open to such officers. This will encourage officers of outstanding ability in these subjects to continue to devote their attention to medicine and surgery, in which previously there were no openings for officers above the seniority of lieutenant-colonel.

The question of specialists has also undergone review and a great improvement in the method of training and selection has been effected. Captains undergo a five months' course at the Royal Army Medical College for promotion to major in the subjects of hygiene and pathology, together with general medicine and surgery. Of those officers who pass the Combined Examination in these subjects, the first 50 per cent. are now eligible to take out a further four months' specialist training, provided that they can prove to have had past experience in a particular subject and to have shown special aptitude for that subject. Results so far achieved by this system have, we are informed, been most encouraging. The training is undertaken by selected teachers of the various London general hospitals, as well as the army professors at the college.

It is recognized that, apart from purely professional work, officers should receive administrative training, and the inclusion of officers of the Royal Army Medical Corps in the

regarded as final, and may require modification as the work proceeds. No reference is made on this occasion to certain histological details, which we hope to bring forward at some subsequent date.

#### Clinical Results.

The clinical material upon which our observations are based was selected to ascertain the character and nature of the nervous contraction at various periods of pregnancy, when the lumbo-sacral cord were innervated by means of spinal anesthesia. The cases include:

- (a) Abdominal Caesarean section, at the eighth and ninth months of gestation for such varying indications as contracted pelvis, placenta praevia, and toxemia.
- (b) Vaginal Caesarean section during the fourth and fifth months of pregnancy.
- (c) Evacuation of the ovum at the second month of gestation.

The technique employed was practically the same in all cases, and is identical with that outlined by us in a previous communication.<sup>11</sup> Briefly, it consists in injecting 1.5 c.cm. of a 5 per cent. solution of ropacocaine (Allen and Hanbury) dissolved in normal saline solution into the spinal theca, by means of a Barker's syringe introduced between the second and third lumbar vertebrae, after 10 c.cm. of cerebro-spinal fluid have escaped from the needle.

When the lumbar cord is paralyzed by the drug, usually in about five minutes, the uterus always contracts, and it does not relax until the drug ceases to act. This is the case, whether a general narcotic—for example, nitrous oxide, ether, or chloroform—is administered in addition or not. Further, the contraction appears to involve the circular muscle fibres of the uterus, the longitudinal being unaffected. In other words, the uterus grips the ovum firmly, and on several occasions before the abdominal incision was made the organ was noted to stand forward and to become markedly prominent.

When the membranes are incised and the liquor amnii has escaped, the uterus contracts down upon the fetus with extraordinary rapidity, and may cause some difficulty in extraction. This is especially the case when the membranes have ruptured before operation, and, in the interest of the child, rapidity of technique is essential.

The lower uterine segment and cervix also appear to be involved in the increased uterine "tone." There is certainly no "polarity," as evidenced by dilatation, and in one instance some difficulty was experienced in extraction of the placenta per vaginam. Previous to operation in this case the degree of dilatation of the cervix appeared such as to warrant expulsion of the placenta *per vias naturales*. This in practice was rendered very difficult owing to the increased tone of the circular muscle fibres of the lower uterine segment. The uterus contracts equally well whether labour has started or not, and in our experience the tied organ, after forty-eight hours of expulsive effort, contracts quite powerfully when the lumbar stimuli are eliminated.

Further, we note that the contractile power is in no way diminished during the earlier months of pregnancy, as was shown by two cases of vaginal Caesarean section at the fourth and fifth months of pregnancy and the evacuation of the uterine contents at the second month. On the other hand, contraction of the circular muscle fibres during pregnancy will not induce labour, as in the case of a patient from whom a large vaginal cyst was removed under lumbar anesthesia during the fourth month of her pregnancy.

The gestation in this case is proceeding normally to term. The contractile power of the uterus under spinal anaesthesia is in marked contrast to what is generally observed when a general anaesthetic is administered. Under chloroform, ether, or nitrous oxide narcosis, alone, however slight or deep, the uterus when induced to contract, by manipulation or otherwise, generally relaxes somewhat after a few moments. This, in our experience, is never the case when the lumbo-sacral cord stimuli are eliminated, the contraction and tone persisting until such stimuli are restored.

With regard to the influence of spinal anaesthesia upon normal labour, we have been rather chary of experimentation owing to our direct observations of the behaviour of the uterus in cases of Caesarean section. As already noted, the uterus in cases of Caesarean section.

it appears to be the circular fibres of the uterine wall, both corpus and cervix, which are inhibited by the lumbo-sacral autonomic system, and for this reason we think that these stimuli should not be cut off until dilatation of the cervix is complete.

In one patient, a 5-para, to whom a spinal injection of ropacaine was given when the os was fully dilated and the membranes ruptured, the second stage of labour occupied one and a half hours. The uterus never relaxed, but, on the other hand, there was no strong intermitting expulsive contractions. The child was expelled, painlessly of course, by means of strong voluntary expulsive efforts on the part of the patient, reinforced by the hand of the medical attendant on the uterus. In other words, the child was partly expressed from the uterus. The placenta was delivered at the end of fifteen minutes and the lochia was less than normal.

The necessity for expression of the child, due to loss of the normal expulsive mechanism under lumbar anaesthesia, is important evidence, in our opinion, of tonic stimuli of the central nervous system normally exerted upon the longitudinal muscle fibres of the uterus.

With regard to operations on the non-pregnant uterus, no contraction of the uterine muscle was noted, and the only observation of interest related to the sensory impulses. When total abdominal hysterectomy was performed under spinal anaesthesia in the absence of adhesions to other organs, we found that it gave rise to very little, if any, shock. Should the organ, however, be adherent to small intestine, considerable shock and discomfort of a vague type are produced. This appears to indicate that the autonomic sensory fibres from the uterus enter the spinal cord below the dorsal region, while sensory fibres from the ileum enter the dorsal region above the narcotized area.

#### Experimental Evidence.

The experimental work in connection with this investigation is being carried out in the Pathological Department of the University of Birmingham with the kind assistance of Professor Haswell Wilson and Dr. A. F. Wright, M.C., to whom we desire to express our indebtedness. The results of certain animal experiments performed for us by Dr. Wright and independently confirmed by him are here recorded.

##### Experiment 1.

Rabbit No. 1; two weeks pregnant. Either narcosis, Laparotomy, and inspection of abdominal contents. Peristaltic movements of intestines well marked; no movements observed in pregnant uterus. Lumbar puncture performed. Ropacocaine (2½ per cent.) injected into lumbar spinal theca. Uterus immediately contracted. Spinal cord severed in upper lumbar region. Uterus contracted further and no subsequent relaxation noted. Dorsal region of cord pinned without relaxation of the uterus. Uterus excited and placed in bath of normal saline at temperature of 37°C. Rhythmic contraction and relaxation occurred for five minutes.

##### Experiment 2.

Rabbit No. 2; three weeks pregnant. Either narcosis, Laparotomy, and pregnant uterus containing seven embryos extra-cerated into normal saline bath at temperature of 37°C. No movements of uterus noted until lumbar cord was narcotized, when permanent contraction occurred. This was increased by injection of ropacaine into dorsal region of cord produced no alteration in the uterine contraction. The dorsal cord was next pinned, without any change. The right half of cord containing the uterine and ovarian vessels and nerves was then clamped and divided. The right uterus immediately contracted. The uterine contents were removed and placed in a warm saline bath. Peristaltic waves of contraction, apparently commencing in the region of each Fallopian tube, continued for several minutes.

##### Experiment 3.

Rabbit No. 3; three weeks pregnant. Either narcosis, Laparotomy, intestines and uterus containing five embryos extra-cerated and placed in warm saline. Lumbar cord pinned without alteration in condition of uterine muscle. Mesenteries divided without effect on uterus. All tissues divided at junction of lumbar and inferior vena cava. The uterus did not relax. The uterus was excised and placed in saline. The temperature of the latter had fallen to 50°C. and no peristaltic movements were observed. The temperature of the bath was raised to 37°C., when rhythmic contraction and relaxation of the excited organ commenced.

##### Experiment 4.

Rabbit No. 4; four weeks pregnant. Either narcosis, Laparotomy; Dystogastric nerve exposed and stimulated by faradic current. This produced contraction of the circular fibres of the uterus, the portion of the organ containing each foetus becoming

## INDIAN MEDICAL SERVICE.

UNDER the new constitution now being brought into effect in India medicine is a transferred subject—that is to say, it will in future be under the control of the Provincial Governments and legislatures. As at present arranged 305 civil posts are reserved for officers of the Indian Medical Service—namely, 65 under the Government of India and 240 under Local Governments. In the present state of transition the position which the Indian Medical Service will in future occupy is not well defined; it seems unnecessary, therefore, to reproduce here in full the conditions of service. Full details and particulars can, however, be obtained from the Secretary, Military Department, India Office, Whitehall, London, S.W.1.

## THE ROYAL NAVAL MEDICAL SERVICE.

## A WARNING TO YOUNG MEDICAL MEN.

IN January, 1920, as a consequence of the report of the Jerram-Halsey Committee, new regulations for retirement of officers came into force in the Royal Navy, and new rates of pay were laid down. The new regulations inflicted a great injustice upon a considerable number of surgeon commanders who were nearing, or had passed, the new retiring age. The grievance arose under two heads—age of retirement and rate of pension—and frequent remonstrances were addressed to the Admiralty by the British Medical Association.<sup>1</sup>

Very briefly stated, these medical officers, who had entered the Service on the understanding that they would be allowed to serve until the age of 55, were compulsorily retired at 50, and their maximum pension was fixed at £600 a year, representing an increase of but 10 per cent. on the former retired pay of their rank; it should be particularly observed that officers of other branches got increases of pension varying from 26 to 100 per cent. In reply to representations by the British Medical Association the Admiralty admitted the grievance, but declined to remedy it. The Council of the Association at length warned the Admiralty that if the question could not be settled satisfactorily it would be obliged to place the facts before the profession, and to advise young medical men that if they entered the Royal Naval Medical Service they must do so with the knowledge that, with its present policy, the Admiralty cannot be trusted to keep any engagement it may make with its medical officers. Therefore, bearing in mind the treatment of senior surgeon commanders, the Association's advice to medical students and young practitioners is to consider seriously the disadvantages to which they are liable if they place their careers in the hands of the Admiralty.

It may be hoped that before next year's Educational Number appears the Admiralty will have seen the wisdom of putting itself right in the eyes of the medical profession. If this is done, we shall be able to include once again a statement of the conditions under which commissions are granted by the Medical Department of the Royal Navy, and in other ways give encouragement to prospective candidates.

## PRISON MEDICAL SERVICE.

CANDIDATES for the medical staff are approved by the Secretary of State for the Home Office on the recommendation of the Prison Commissioners. The Chairman of the Board is M. L. Waller, Esq., C.B. Application for employment may be made to the Board on a special form, which can be obtained from the Secretary, Prison Commission, Home Office, London, S.W.1.

In the smaller prisons the medical officer is usually a local practitioner, but in the larger the members of the medical staff are required to devote their whole time to the service. In the case of those required to give their whole time to the service the appointment in the first instance is to the post of medical officer Class II, and from the seniors of this rank the medical officers Class I are selected as vacancies occur.

The pay of the whole-time prison medical staff is: Medical officer Class II, £300, rising by annual increments of £15 to £500; medical officer Class I, £550, rising by annual increments of £20 to £700. Unfurnished quarters are provided, or an allowance in lieu is made. The Civil Service bonus is

paid on the salary. There are 15 medical officers Class II, 10 medical officers Class I, and 33 part-time medical officers.

The number of vacancies is never large, and promotion is slow. Although there has recently been some improvement in the scale of pay, the remuneration both of whole-time and part-time prison medical officers is unsatisfactory. A Committee is now inquiring into the pay, etc., of prison officers (including medical officers) and its report is expected to be issued this year.

## MEDICAL PRACTICE IN BRITISH DOMINIONS AND FOREIGN COUNTRIES.

MEDICAL Acts have now been passed in almost all places forming part of the British Empire beyond the seas, and registers of duly qualified practitioners are consequently maintained. To these registers medical men educated in the United Kingdom are always admissible merely on payment of a registration fee, providing they produce evidence that they are of good repute and are either registered or eligible for registration in the United Kingdom, as the local requirement may be. The only exception to this statement that need be made relates to the Dominion of Canada. Each of its provinces acts in medical matters as an independent State. The result has been that reciprocity of practice has been established between this country and all the Provinces of Canada except British Columbia, where certain obstacles still remain to be overcome. We would advise any medical man proposing to practise in Canada first to communicate with the Provincial Registrar, stating what degrees or diplomas he holds, and asking for information as to the precise steps he must take in order to obtain admission to the Provincial Register.

Italy and Japan are the only two foreign States with which complete medical reciprocity has been established, though there are other countries which grant a limited recognition to British qualifications. Generally speaking, in Continental countries (with the exception of the kingdom of Italy) a British medical man desiring to exercise his profession therein must pass practically the same examinations as those imposed on natives of the country. The same observation applies to all foreign States in the South American continent. Each of the United States of North America has its own laws and regulations governing medical practice; some of the States admit any holder of a degree or diploma to their Register, but the majority require a candidate for registration to submit to an examination.

A pamphlet showing the conditions under which medical and dental practitioners legally qualified in their own country may practise abroad can be obtained from the office of the General Medical Council, 44, Hallam Street, Portland Place, London, W.1, price 2s. 6d., or 2s. 9d. post free in the United Kingdom. Practitioners who think of going abroad to practise will find therein much useful information, including the name of the official in each country to whom requests for further particulars should be addressed. The last edition was published in January, 1921.

## MEDICAL APPOINTMENTS UNDER THE COLONIAL OFFICE.

APPOINTMENTS to the Medical Services of the Colonies and Protectorates under the administrative control of the Colonial Office are made by the Secretary of State for the Colonies. Such appointments are to the service of a given colony or colonies, for there is no unified service directly administered from the Colonial Office. It follows that conditions of service and superannuation are in the main determined by the economic resources and general public health policy of the individual colony and its local government, and vary almost as widely as do conditions of climate. Moreover, the extent of the control exercised by the Colonial Office varies according to the constitutional status of the particular colony, and the detailed information available centrally is not always complete. The intending candidate, therefore, should make comprehensive inquiries as to local conditions before applying for an appointment, and will do well to supplement official information by reference to the central office of the British Medical Association, where reports obtained from time to time from the local Branches are available. This is the more necessary

<sup>1</sup> See BRITISH MEDICAL JOURNAL, July 8th, 1922 (p. 52).

THE TREATMENT OF SEVERE UTERINE  
HAEMORRHAGE BY RADIUM.

SIDNEY FÖRSDIKE, M.D., B.S., F.R.C.S.,

·πορροτ

[illegible][illegible][illegible]

In a paper read before the Gynaecological Section of the Royal Society of Medicine in March, 1923, I analysed the results of 45 cases treated by radium, and I have only to add to that report that three of the patients had a recurrence of haemorrhage from eight to nine months after treatment, in one of whom it was so slight as to require no further attention; the other two had each a further exposure, which sufficed to re-establish amenorrhoea. The report on the remainder requires no comment.

I have now treated 65 cases in all of this severe type of haemorrhage, 43 of which had undergone some form of operation, dilatation and curetting being the commonest, and no patient being cured less than five times; two patients had been cured three times, and several had undergone the process twice. The other operations noted in the history were excision of polyp, amputation of the cervix, excision of cystic ovaries, salpingectomy, and appendectomy. The remainder were compelled to spend some part of each month in bed or had become so anemic that further treatment was imperative. Seven of the cases were associated with small mural or submucosal fibroids, which responded equally well to the treatment, and on no detectable change was found in the size of the submucosal fibroids on examination some months after treatment.

5. Both autonomic and sympathetic stimuli are controlled by higher centres in the medulla and possibly the cortex, but are capable of acting independently of the same.

6. Reflexes, both (a) autonomic and (b) sympathetic, are (Reference may be made to mammalian and perfused stimulation.)

7. Uterine contractions, to be effective, depend equally upon the integrity and correctly adjusted balance of autonomic and sympathetic impulses. Disturbances in either, whether in the direction of augmentation or diminution, will interfere with the normal course of parturition.

### Practical Application of Results.

Advantages of lumbar narcosis, either alone or combined with general anæsthetic, are evident. By elimination of inhibitory stimuli from the lumbar cord and allowing the corresponding full play, the cerebral muscles fibres of the motor cortex are not overstimulated, and no doing repeated homogeneous damage to a negligible amount. In one of our cases the spinal cord was removed at a level just above the level of the contraction of the circular muscles, producing marked eversion of the edges of the nerve and this is normally present, but no overstimulation of the cut surfaces is facilitated.

the placenta. Subsequently it would be increased, owing to greater separation of the lower uterine segment, it is probable that the placenta would be controlled for the time being by contraction of the placental vessels, and although the placental vessels are separated by a certain amount of tissue, it is possible that this may be obtained without separation of the placenta. It is possible that the placental vessels are separated from the uterine wall by a certain amount of tissue, and that this may be obtained without separation of the placenta. It is possible that the placental vessels are separated from the uterine wall by a certain amount of tissue, and that this may be obtained without separation of the placenta.

to evaluate the uterus by the vaginal route during pregnancy. For the same reason we do not recommend the use of the placental site. For the same reason we do not recommend the use of the placental site. For the same reason we do not recommend the use of the placental site.

[illegible]

the employment of spinal anaesthesia in normal cases of labour. By its use dilatation of the cervix will be delayed, and even if administered at the commencement of the "second" stage, the expulsive power of the uterus is diminished. Consequently forceps delivery with its attendant risks will in all probability be required.

## REFERENCES:

[illegible]

The President congratulated Mr. Beckwith Whitehouse on his very fine paper. It was not a paper which lent itself to discussion; time was required in order to read it and follow it out in detail. He was much interested in the subject of the contractions of involuntary muscle. His attention had been directed to the contractions of the intercostal musculature; frequently with spinal anaesthesia in cases of paralytic obstruction the intestine would evacuate

consult the Colonial Office List and the Professional Handbook (price 6d.) issued by the Overseas Settlement Office, 6, St. James's Square, S.W.1.

There remain a number of medical appointments made by mining companies and other commercial undertakings in various parts of the tropics. Much caution should be exercised in accepting such posts, and the form of contract should be subjected to very careful scrutiny. Advice in this connexion should always be sought at the central office of the British Medical Association, 429, Strand, W.C.2.

## MEDICAL RADIOLOGY AND ELECTROLOGY.

### THE CAMBRIDGE DIPLOMA.

A Diploma in Medical Radiology and Electrology is granted by the University of Cambridge. The primary object is to provide adequate training in a branch of medical work which is becoming increasingly important and difficult, and which is outside the ordinary medical curriculum. The Diploma is only open to those who hold a medical qualification, and includes a course of lectures and practical work in Physics (Part I) and in Radiology and Electrology (Part II). Attendance at the necessary courses of lectures in both subjects, and in addition six months' clinical experience in an adequately equipped hospital recognized by the Committee, is essential. The whole course of study takes six months, the lectures, practical work, and hospital attendance running concurrently.

The courses carried out by the University of Cambridge are at present arranged to begin early in January. Three months are spent in Cambridge doing the lectures and practical work in Part I, and attending the systematic lectures in Part II and the practice of Addenbrooke's Hospital, where there is a fully equipped and up-to-date X-ray and Electrological Department. The remaining three months can be completed at any recognized hospital, but special arrangements are made for students to continue their studies in London, where demonstrations at various hospitals are arranged, in order to give a wide experience.

In addition, an independent course is arranged by the British Association of Radiology and Physiotherapy. This course is held entirely in London, but is recognized by the University as qualifying for the examination; it begins early in October.

Further particulars as to the Cambridge Course can be obtained from F. Shillington Scales, M.A., M.D., Medical Schools, Cambridge, and of the London Courses from Stanley Melville, M.D., at the offices of the British Association of Radiology and Physiotherapy, 12, Stratford Place, London, W.1.

## MEDICAL MISSIONARIES.

Missionary Societies are in constant need of qualified men and women to fill vacancies as they occur in their hospitals, and also to enable them to take advantage of fresh openings. To those suitably endowed the mission field offers unique opportunities for interesting work, and the development of native medical schools, as training institutions in connexion with some of the larger mission hospitals, affords excellent scope for valuable work to medical men and women who are qualified to teach. It is not usually expected that medical missionaries should take a position such as would otherwise be occupied by an ordained clergyman or minister, but it is essential that they should be prepared to exert their influence in any hospital to which they may be sent so that a Christian atmosphere may be maintained and the work of evangelization be carried on through the ministry of healing.

As for scientific and other qualifications for the work, medical missionaries, in addition to being physically capable of sustaining a life which makes a great demand upon their strength, should be thoroughly well trained physicians and surgeons. It is very desirable that they should have held a resident appointment at a general hospital, and have a good knowledge of practical surgery, gynaecology, tropical medicine, and the treatment of eye diseases. Useful information can be obtained from the Secretaries of the various Missionary Societies, or from Thomas Cochrane, M.B., O.M., Honorary Secretary, British Advisory Board on Medical Missions, 3, Tudor Street, London, E.C.4.

## Dental Surgery.

UNTIL the passing of the Dentists Act, 1921, the profession of dentistry in this country was regulated by enactments very closely similar to those relating to the practice of medicine—that is to say, there was no direct prohibition of the act of practice; and the Dentists Act of 1878 gave the same degree of protection to legally qualified and registered dentists as was accorded to registered medical practitioners—namely, the reservation of the use of certain titles. This Act also provided (1) that no person should take or use the name or title of "dentist" (either alone or in combination with any other word or words) or of "dental practitioner," or any other name, title, or description expressed in words or by letters implying that he was specially qualified to practise dentistry, unless he was registered, under a penalty of £20; and (2) that an unregistered person could not recover any fee or charge in respect of any dental operation, attendance, or advice. But, in the case of the practice of medicine by unqualified and unregistered persons, certain deterrent factors came into play—such as the inability to give a death certificate—and these did not operate to the same extent in the case of dentistry; hence, unqualified practice has been far more prevalent in dentistry than in medicine, and this increased after a decision of the House of Lords placing a narrow interpretation upon the words "specially qualified to practise dentistry," by defining the word "qualified" as not referring to competence but to the possession of a recognized diploma.

### THE DENTISTS ACT, 1921.

This unsatisfactory position has now been remedied by the passing into law of the Dentists Act, 1921; its provisions are based largely on the recommendations of a Departmental Committee appointed in 1917 by the Privy Council "to investigate the extent and gravity of the evils connected with the practice of dentistry and dental surgery by persons not qualified under the Dentists Act." Since November 30th, 1922, no person has been permitted by law to practise or hold himself out, whether directly or by implication, as practising or as being prepared to practise dentistry unless he is on the *Dentists Register* provided for by the Dentists Act, 1878. The practice of dentistry is defined as including "the performance of any such operation and the giving of any such treatment, advice, or attendance, as is usually performed or given by dentists," and the performing of any operation or the giving of any "treatment, advice, or attendance on or to any person as preparatory to or for the purpose of or in connexion with the fitting, insertion, or fixing of artificial teeth." The maximum penalty incurred by an unregistered dentist is £100 for each offence. There are, however, certain important exceptions to the requirement of registration. A registered medical practitioner may practise dentistry without being on the *Dentists Register*, and a registered pharmaceutical chemist or chemist and druggist may extract a tooth where the case is urgent and where no doctor or dentist is available, but the operation must be performed without any kind of anaesthetic; further, any person may carry out minor dental work in a public dental service under the personal supervision of a registered dentist provided it is in accordance with conditions approved by the Minister of Health after consultation with the Dental Board.

Certain persons other than those qualified by examination were entitled to be registered under the new Act. They had to be of good personal character and 23 years of age before July 28th, 1921 (the commencement of the Act), and to have been engaged for five (the seven years preceding that date as their principal means of livelihood in the practice of dentistry in the British Islands, or have been admitted to membership of the Incorporated Dental Society not less than one year before the commencement of the Act. The passing of "the prescribed examination in Dentistry" within two years of the commencement of the Act is considered as equivalent to practising for five years, and a registered pharmaceutical chemist or a chemist and druggist who immediately before the commencement of the Act had a substantial practice as a dentist, including all dental operations, was treated as though he had practised for five years. A dental mechanic who for the five years has been carrying on his work as such can be registered provided within ten years of the commencement of the Act he passed the prescribed examination. Dentistry may be carried on by a corporate body provided the

# MENORRHAGIA TREATED BY INTENSIVE X-RAY THERAPY.

REPORT OF TWENTY CONSECUTIVE CASES.

L. MARTINDALE, M.D., B.S.LOND.

LONDON.

Since last September I have adopted a modification of the Ewing technique in the treatment of uterine haemorrhage, whether such be due to the climacteric, or to fibroids, tumours of the uterus, or to fibrosis of the uterus, as well as for cases of carcinoma and sarcoma, either after or instead of operation. I have been so impressed with my own results, as well as the results I have seen abroad, that I venture to lay before you a short report of twenty cases of fibroids and climacteric haemorrhage treated by myself by this new technique, comparing them with twenty consecutive cases I did by the Ewing method some years ago. Although these represent only a very small proportion of the cases I have done with the new technique, I feel that my report on my carcinoma cases would be on work done too recently to be of any statistical value. I must also confess that I am still doing a large number of myomectomy, hysterectomy or panhysterectomy for fibroids. In all cases of doubtful diagnosis I do a diagnostic curetting. In cases of tumours reaching above the umbilicus I am also, still doing hysterectomy; also in some cases in which I have diagnosed pedunculated subperitoneal fibroids or in which the symptoms make me believe that there may be some degeneration, malignant or otherwise, of the fibroid tumours.

Surgical treatment is to me sometimes a temptation; hysterectomy or myomectomy and the cases do so well; one never feels that I am actually seeing for oneself at the operation the uterine condition. On the other hand, I suppose most surgeons still have to confess to a 1 per cent. mortality even for hysterectomy for fibroids. Gauss of Freiburg, who is an excellent surgeon, uses x-rays in practically all his cases of fibroids and in all cases of carcinoma of the cervix; in fact, when I saw him at work last year I found he only refused to x-ray a fibroid when it was complicated by very urgent pressure symptoms. He goes so far as to say that in doubtful cases he would even do an exploratory laparotomy. If only a small fibroid were present and a myomectomy would suffice he would do a myomectomy, but never a hysterectomy. He would close the abdomen and use x-rays instead.

The new technique, which I must remind you involves only one, or at most two, treatments, lasting about two and a half hours. I have employed apparatus on the double coil principle, said to work at a voltage of 200,000, and capable of generating an extremely hard, penetrating radiation, which, when filtered, is practically homogeneous.

I moved to my present house for the sake of its well lighted and airy x-ray room, and I work from an anti-room protected by 5 mm. thick lead screening. By means of a specially constructed fan ventilator the air of the room is always fresh, and much of the Roentgen sickness complained of by some radiologists is therefore avoided.

## Precision of Dosage.

The chief characteristic of the new technique is precision of dosage. This involves:

1. Knowledge of the exact biological unit skin dose of every tube.
  2. Knowledge of the percentage depth dose of every x-ray tube employed.
  3. Knowledge (and this is only gained by exact experimentation) of the best filtering for each tube so as to obtain the highest point of homogeneity.
  4. Measurement of the coefficient of absorption of each tube in those cases in which Dessauer's curves are used.
- These measurements have to be made for each tube certainly every fourteen days, and it is extraordinary how much variation one finds, but it is only with this exact knowledge that one can work with such intense doses with any degree of safety.

Mr. Beckwith Whitehouse (Birmingham) thought that these cases were very difficult to treat. He cited an instance where he had used radium, but the haemorrhage did not stop and the patient died. Subtotal hysterectomy would probably have saved her. He agreed with the President that multiple curettage was a dreadful mistake. He thought that radium might act by holding up the function of the endometrium, possibly destroying its hormones, until the full development of ovarian function. If the endometrium were found to be atrophic after diagnostic curettage, radium would probably do good. He wondered whether, in those cases of Dr. Forsdike's where ovarian changes had been demonstrated, these changes could be ascribed to atrophy of the endometrium rather than to the direct action of the radium.

Dr. W. R. Grove (St. Ives) believed that many of these cases would be found to have calcium deficiency. He had come to the conclusion that calcium deficiency was evidence of blood sepsis, preventing healthy healing and predisposing to the manifestation of disease in the patient's weakest spot. A chronic eczema would frequently be healed if calcium deficiency could be established. If an intramuscular injection of 1 gram of calcium chloride were repeated daily for two or three days haemorrhage would probably cease, but parathyroid extract was the only thing by means of which permanent calcium efficiency could be maintained.

Dr. John Caspary (Belfast) had been very disappointed in the use of radium in cases of uterine haemorrhage. He was interested to hear that radium produced atrophy of the endometrium. Thirty years ago nitric acid and other agents had been employed to achieve the same purpose. He had been in hopes that radium might supplant operation in the case of the smaller fibroids, but he had found that it was not so. Surgery had not lost its place even with small fibroids. He had seen astute following the use of radium in several cases, but in only one was the fibula permanent—the others healed spontaneously without the need of operation.

Dr. Russell Green (Birmingham) thought the comparison of radium therapy to the action of a red-hot poker both fortunate and unfortunate. It was unfortunate because it obscured the idea lying behind radiation methods—namely, that a selective action could be exerted. It was fortunate because it illustrated the fact that, in order to produce an effect even slightly remote from the point of application of radium, a much greater dose must be given at the point of application. If the dose required was a fairly big one, the radium dosage delivered from a remote point was very greatly larger, and then there was the danger of oversteering. The Ewing-Rankin technique had been evolved to avoid, and did avoid, this danger inseparable from radium therapy.

Dr. James Hewary (Glasgow) asked Dr. Grove whether he could produce evidence that in these cases of menorrhagia that Dr. Forsdike did not include the menorrhagia of puberty in his cases. In very young girls these severe haemorrhages generally cleared up with simple medical treatment without the use of radium.

Dr. Forsdike, in reply, said that he was afraid that the discussion had become discursive. His cases had been limited to those which had already been treated in a variety of ways without result. He had never had occasion to treat a girl at puberty—they usually got well of themselves. If radium were placed in the vagina it was very likely that a fistula would be produced if the radium were left in long enough. His point was that radium placed in the uterus as he employed it could not cause a fistula. It was the gynaeecologist, and not the radiologist, who should use radium on the female genitalia. The ovarian changes he had demonstrated were so gradual that he could not ascribe them as due to the changes produced on the endometrium. In the 65 cases in which he had used it radium had never failed if do what was required of it. In young patients he thought that they should aim to bring about a modification of the haemorrhage rather than completely to abolish it.

course should comprise a minimum of sixteen meetings of the class. (e) Dental Metallurgy (with practical work and demonstrations). The course should comprise a minimum of twenty meetings of the class. (f) Dental Mechanics (with practical work and demonstrations). The course should comprise a minimum of twenty meetings and twenty demonstrations. (g) A course of instruction in the use of Anaesthetics, general and local, employed in Dental Practice. (h) A course of instruction in Radiology as applied to Dentistry.

(vi) That he has for at least twenty-four calendar months attended, during the ordinary academic terms, the practice of a recognized dental hospital or of the recognized dental department of a general hospital.

(vii) That he has received for not less than twenty-four calendar months, or for 2,000 hours, practical instruction in dental mechanics.

5. That the examination for a degree or licence in dentistry or dental surgery shall be partly written, partly oral, and partly

practical, and shall include the following subjects: (a) Chemistry, Physics, and Biology, in their bearing on Medicine and Dentistry. (b) Human Anatomy, and Physiology. (c) General Pathology, including Bacteriology. (d) Medicine and Surgery. (e) Anatomy and Physiology, Dental Pathology, Dental Surgery (including Orthodontics), Dental Materia Medica and Therapeutics, Dental Mechanics and Dental Metallurgy. (f) Practical Examination in Dental Surgery. (g) Practical Examination in Dental Medicine and Metallurgy. (h) Anaesthetics, general and local, employed in Dental Practice.

6. That the prescribed subjects of examination may be carried out or distributed at the discretion of the licensing bodies, and may be taken at two or more successive stages during the course of professional study; provided that no candidate shall be admitted to the final examination in Dental Surgery and Dental Mechanics unless he shall have completed the required four years' course of study.

## The British Medical Association: ITS AIMS, WORK, AND CONSTITUTION.

THE British Medical Association (as briefly stated at the close of our introductory article on the Profession of Medicine) was founded in 1832 to promote the medical and allied sciences, to maintain the honour and interests of the profession, and foster a feeling of friendship among its members. To attain these objects it holds periodical meetings for the discussion both of medical and scientific subjects, and of professional affairs; it publishes the *British Medical Journal*; it maintains a reference and lending library; it has instituted lectures, scholarships, and grants for research work; and does an immense amount of work on behalf of practitioners. The British Medical Association, with a membership of more than 25,600, is the oldest, largest, and most powerful British organization devoted to the welfare of the medical profession. It has recently acquired a fine building in Bloomsbury for its headquarters, providing ample accommodation for immediate needs and space for future developments. The remarkable growth in the central work of the Association during recent years has far outstripped the capacity of the present premises at 429, Strand. An account of the steps taken to acquire, on most advantageous terms, the handsome building designed by Sir Edwin Lutyens, R.A., was given in our issue of July 7th, 1923, at pages 28 and 33.

### Constitution and Administration.

The Association has Branches and Divisions throughout Great Britain and Ireland, and also in the Dominions, Colonies, and Dependencies. The Divisions are arranged territorially, and number, in all, 277. For certain purposes of administration or of scientific and clinical work, the Divisions are combined into 93 Branches. Members of Divisions elect Representatives on the Branch Councils and also a member or members of the Representative Body, which is the governing body of the Association and determines its policy.

The Council is the executive of the Association. It is elected partly by the Divisions and Branches and partly by the Representative Body, and includes representatives of the Navy, Air Force, Army, and Indian Medical services elected by the Representative Body. The Representative Body and Council elect standing Committees to take charge of different subjects. Among these may be mentioned the Science, Medico-Political, Ethical, Hospitals, Public Health, and Naval and Military Committees. There are Committees also for the Dominions, Scotland, Ireland, and Wales; and for the working machinery of the Association, such as the Organization, Finance, and Journal Committees. The Insurance Acts Committee, elected partly by the Association and partly by insurance medical practitioners, is financed by the Association; it is the recognized executive and mouthpiece of the insurance practitioners of Great Britain.

### Privileges of Members.

A member of the British Medical Association has the right—

1. To attend the annual and other general meetings of the Association and the meetings of the Division and Branch to which he or she belongs.

2. To take part by personal vote (or in some Divisions by voting paper) in the election of the representative of his or her Division in the Representative Body, and also in the election

3. To receive by post the *British Medical Journal*, published weekly, which gives a full record, with commentary, of progress in clinical and scientific medicine, and of medico-legal affairs throughout the British Empire.

4. To receive the help and advice of the central office in professional difficulty.

5. To use the library as a reading room, and to borrow current medical or scientific books on payment of postage. Besides modern works and periodical medical literature, foreign as well as English—the library contains many books of historic interest.

The full benefits of the Association can only be secured by the co-operation of large numbers of the medical profession, who by their annual subscriptions provide the necessary funds. The greater the membership and the funds the more efficient and influential the organization. The Association during the past ninety years has been the direct benefactor of every class of medical men and medical women. In asking for new members it looks not only to the practitioners but also and especially to those recently qualified. To these a generous concession is made as regards subscription, and there is a special claim to their recognition and work of the British Medical Association in improving conditions under which they may hold appointments in public services or in civil life. The Association's work in the Services is well known. It considers itself to be in a special sense the guardian of the interests of those members of the profession who by reason of their position are prevented from taking common action. At the present time, nearly all the Imperial services are being cut down in numbers and in remuneration, it is ordinary prudence for every medical officer to join his professional organization.

### Subscriptions and Applications for Membership.

The ordinary subscription to the British Medical Association is 3 guineas a year for members resident in the United Kingdom, but this is subject to various exceptions. Newly qualified practitioners elected within two years of registration pay half this sum up to the end of the first year after registration; medical officers on the active list of the R.N., R.A.F., R.A.M.C. (Regular), and I.M.S. pay 2 guineas. Concessions are made also to members (in the British Isles) of forty years' standing, to members of ten years' standing who have retired from practice, to medical married couples residing together, and to whole-time teachers and research workers. The ordinary subscription for members abroad is 1½ guineas, but some Branches have special rates. A member elected after June 30th in any year pays for that year one-half the current annual subscription.

All duly qualified British medical practitioners are eligible for election as members. Full particulars can be obtained on application to the Medical Secretary, British Medical Association, 429, Strand, London, W.C.2; the Scottish Medical Secretary, 19, Rutland Square, Edinburgh; or the Irish Medical Secretary, 16, South Frederick Street, Dublin.

[The present issue being the Annual Educational Number, all current material is held over, and neither the "Supplement" nor the "Epitome of Current Medical Literature" is published this week.]

THE BUTLER  
MEDICAL JOURNAL  
413

The President said the subject was too big for the Section to discuss fully in the limited time available. He had to confess at the outset that he had no use at all for x-ray treatment. He could remember the days when the ovaries were extirpated with the idea of curing fibroids, and it seemed to him that x-ray treatment was a return to those methods of barbarism. He had always, even before the war, had a profound distrust of Germans, and did not believe their results. Castration for gonorrhoea seemed to him to be gynaeceology made, and similarly x-ray treatment for prostatic hypertrophy he was immensely in favour of myomectomy. He had seen the most violent menopause symptoms produced in young women by x rays. He had recently had a case of the most diffuse cellulitis of the abdominal wall set up by exposure to x rays. He looked upon x-ray treatment of fibroids as a most retrograde step, and when operation was attempted after their use the difficulties were increased a thousandfold.

Dr. Forsdike (London) confessed that he had not realized the depths of his ignorance until he listened to Dr. Martindale's paper with its maze of technicalities. He repeated—that in his view all forms of radiation were absolutely contraindicated in the presence of pelvic peritonitis. He had clearly demonstrated that the ovary never recovered if radiation was pushed to the point of castration—temporary castration was impossible.

Mr. Beckwith (Warrimoor) wished to associate himself entirely with the remarks made by the President. He regarded castration as most emphatically a retrograde step. He asked Dr. Martindale whether she had observed any cases of severe anaemia from destruction of red cells following x-ray treatment.

Dr. Martindale, in reply, said that she did not think it was quite fair to compare her results with the tragedies quoted by other speakers. She had had no cases of severe anaemia; her patients had all been wonderfully improved.

DISCUSSION.

...to life.  
home or hospital, and, above all, a treatment involving no

precincts were numerous scars in both apices. The heart was markedly hypertrophied, but the valves were normal. Macroscopically, the thoracic aorta showed no abnormalities. The intestines were grossly dilated with no abnormalities.

Incision of the peritoneum revealed a large blood clot reaching to the upper pole of the right kidney and downwards into the pelvis. The ascending colon had been contracted and fixed into the

## NEUROSES— THE FIRST THERAPEUTIC STEP.

**I**T is becoming increasingly evident that there is no such thing as psychic disorder apart from corresponding disturbance of the physical mechanism. We are being driven to the belief that there is a psychology of the cell as significant as and even more fundamental than what we may call the collective psychology of the individual, to which the term has, so far, been generally applied.

Equally it is questionable whether any bodily derangement occurs without parallel mental disturbance.

It is a matter of general experience that the neurotic individual nearly always is troubled with dyspepsia and constipation. So frequent, indeed, is the association that by some they have been thought to be cause and effect. Such, however, is probably but a crude explanation of the coincidence.

What is certain is that attention to the alimentary system may wisely precede and accompany all other psycho- and physico-therapeutic measures for the relief or cure of neuroses. Drastic purgatives, it is true, are generally most undesirable in these cases, but many physicians have found a most valuable adjuvant, in dealing with neurosis, in ENO's "Fruit Salt." This preparation can safely be entrusted to the patient, being meticulously pure, free from all harsh mineral salts, and pleasant to take, yet thoroughly efficient in action.

*THE proprietors of ENO's "Fruit Salt" will consider it a pleasure to send to any member of the Medical Profession for his personal use a bottle (Handy or Household size, as desired) of their preparation, with a copy of the "Doctor's Pocket Remembrancer." This summarises briefly a few points in the diagnosis of nervous diseases which often slip the memory. Bound in black morocco limp.*

fimbriae and pus leaking from the abdominal ostium. Plastic lymph adheres in flakes to the peritoneal surface of the tubes and neighbouring viscera, such as the ovaries and uterus. Organized adhesions have not yet had time to form.

Each tube should first be slit up as far as possible along the border opposite to its mesenteric attachment, the pus very gently swabbed away, and the mucous membrane carefully inspected. Should it appear intact to the naked eye, only congested without ulceration or greyish patches of necrosis, the tube should be left *in situ* without any further treatment beyond a few sutures of thin catgut to fix the muco-cutaneous surfaces at any point where there is arterial bleeding. Any cyst in the ovaries should be opened freely to prevent the formation of an ovarian abscess; a drainage tube is placed to the bottom of the pouch of Douglas, and the abdomen is closed, or drainage may be provided through the vagina.

The advantages of laparotomy and salpingostomy are as follows:

(1) A check is given to spreading peritonitis and the formation of adhesions and peritoneal abscesses by opening and draining the pelvis.

(2) The laying open of the tube drains its lumen and immediately offers it the chance of resolution without the risk of further permanent changes caused by a continuation of suppurative inflammation.

The suppurating tube must be regarded as an abscess cavity with an imperfect drainage through the abdominal ostium. So long as the drainage is imperfect the destructive suppurative process will continue as in an ordinary abscess cavity, with the production of necrosis and desquamation, the formation of adhesions within the tube and sealing of the ostium. But salpingostomy will provide complete drainage, and thus allow immediate retrogression of the inflammatory process, for there is no slough to separate, and the function of the tube may thus be restored.

(3) Salpingostomy obviously renders the formation of a pyosalpinx impossible, and permanent thickening of the tubal wall extremely unlikely.

**Salpingectomy.**—If after laying open the tube the mucous membrane shows grey patches of ulceration and gangrene it is beyond the power of functional recovery and should be removed. The only possible object of preserving the tubes is to maintain their function, and if this appears impossible owing to the extent of their destruction the tubes should be completely removed. By this operation there can be no further salpingitis, and the ovary is saved considerable risk of infection. To leave the tube alone and merely drain the pelvis is to invite the formation of chronic tubal disease and permanent ill health. Further, the convalescence will be longer and more likely to be disturbed by residual abscesses.

#### Results.

It is only very rarely that it is possible to inspect the distant results of salpingostomy done for the acute form of salpingitis. A case in which this was possible made a great impression on me, and is worth recording to show the complete degree of possible resolution.

The condition operated on was one of acute puerperal salpingitis, a notoriously severe form of the disease, in which the tubes were greatly congested, enlarged, plum-coloured, and were oozing pus. They were treated by salpingostomy. The whole of each tube was slit up as far as the isthmus, and the abdomen drained from above.

About three weeks after the operation the patient died of pneumonia and a partial *post-mortem* examination was made. The tubes were carefully inspected, and were found to have undergone complete resolution. The tube wall was soft and of normal appearance, without any congestion, while the gutter made by the operation was found to be clear of any adhesions and opening freely into the pelvic cavity. Moreover, the plicae of the mucous membrane had entirely regained their ordinary appearance.

Such a tube we know from other experience to be capable of bearing ova to the uterus, and so justifying its preservation. How far it is usual for so complete resolution to follow acute suppurative salpingitis with the crowning success of a subsequent pregnancy it is impossible to say, for I doubt if anybody has yet done sufficient operations of this kind, but cases are on record of pregnancy following

salpingostomy of the tube in a chronic state, and it is reasonable to hope that similar treatment of the acute tube sufficiently early, before too great damage of the mucous membrane has occurred, will be followed by similar success.

Even suppose, however, that salpingostomy does fail to produce resolution and a functioning tube, we have done no harm by not removing the tube in the early stage, inasmuch as it cannot lead to a chronic pyosalpinx, and adequate drainage of the pelvis will prevent residual peritubal abscesses.

If, on the other hand, the tube is damaged beyond hope of repair, as by gross ulceration of the mucous membrane, salpingectomy is the only procedure which will preserve the pelvis from future pathological conditions. To leave such cases unoperated upon will ensure the formation of a subsequent pyosalpinx or chronic interstitial salpingitis.

One final word. Many cases of acute salpingitis occur in young women soon after marriage, in whom the certainty of future sterility is a very real tragedy. We are sometimes apt to regard the "recovery" of the patient as the chief if not the only aim of our treatment. Now I claim that our treatment should be designed for further results than "recovery." These (non-puerperal) patients will frequently recover whether the gynaecologist is present or not, but if our treatment is not intelligent and prospective we condemn a young woman to the prospect of certain sterility and frequently to pelvic invalidism. If the tube is treated early, salpingostomy will give her the chance of further childbirth, and if it is already too much damaged, salpingectomy will prevent permanent ill health.

#### II.—VICTOR BONNEY, M.S., M.D., F.R.C.S.,

Obstetric Surgeon, Middlesex Hospital.

I AGREE entirely with Mr. Bourne's proposal to leave out of discussion puerperal salpingitis, the propriety of immediately operating upon which nobody, I suppose, contests. I wish he had called it "post-abortion salpingitis," for salpingitis, though common after abortion, is rare after full-time delivery, because there is no communication between the tubes and the uterine cavity for some time after labour. Cases diagnosed as puerperal salpingitis are usually examples of thrombo-phlebitis of the leash of veins and lymphatics which accompany the ovarian artery in the upper broad ligament, the tube being stretched sessile over the mass so formed.

I have been for a great many years an advocate for operating on all cases of salpingitis at the earliest possible moment. My opinion on this matter has not been lightly formed, for I was brought up in that older school of thought which denounced early operation, and it is always difficult to break away from the teaching impressed by one's seniors at an age when the mind is mouldable. Indeed I know some men who have never recovered from their teachers.

In the nineties I well remember how every female medical ward at Middlesex Hospital perennially contained two or three cases of "perimetritis" undergoing "treatment." Each patient stopped there for weeks with a see-saw temperature chart, and a poultice on her abdomen. I recall that some died, but the majority eventually got well after a discharge of pus per rectum, and after weeks of suffering resumed their normal mode of life.

Later on it became the practice, after the first fury of the attack had spent itself, to transfer these cases to the gynaecological ward and to operate on them. The operation was always severe, sometimes most formidable, and the appendages the surgeon dislodged from the pelvis were a couple of swollen, ragged, pus-exuding masses bearing no likeness to the normal ovaries and tubes as fashioned by Nature's beautiful handiwork. Both appendages were then habitually removed, and, indeed, in very few of the cases could the surgeon have done otherwise. Drainage had often to be maintained for several weeks, and faecal fistulae were common. The mortality attached to these cases of delayed operation was high, and it remains high, for unfortunately patients with neglected salpingitis are still all too frequently presented to us.

More than occasionally, too, I saw cases where opening the abdomen, after days or weeks of suffering, revealed a

of the most important military and naval operations of the war, and the part played by Australia in the war was indisputably magnificent. The volume is well illustrated by maps and photographs and includes an admirable index.

It is a pity that the volume is so small, considering the importance of the subject, and that it is so late in coming out. It is a pity also that the volume is so small, considering the importance of the subject, and that it is so late in coming out.

GUY'S HOSPITAL REPORTS.

Under the title of *Youth and the Race*—the Fourth Report of the National Birth Rate Commission, 1920-23, with the chief evidence, has been published under the editorship of the secretary, Sir JAMES CLARKE. The inquiry was conducted by a body of forty members, of whom fourteen belonged to the medical profession, and the evidence was given by thirty-one witnesses representing psychology, education, and medicine. The report, which precedes the evidence, is divided into two parts, the first dealing with the moral education of youth and the second with the social responsibility of the race. It is an important and an interesting contribution to a psychological inquiry on this subject is now being carried out at University College; the results, it is hoped, will be published this autumn.

The monograph is by Professor Ludwig Zentgraf, head of the children's department of the Vienna General Hospital, is divided into four parts. The first is devoted to orthostatic edematous albuminuria, a subject on which he is well known authoritatively; the second to functional nephritides, a term applied to atypical forms of orthostatic albuminuria; the third to renal dysplasias, including acute and chronic nephritides, nephroses, and nephroses of the kidneys; paroxysmal hemoglobinuria, and hyaline casts of the kidneys; and the fourth to diseases of the urinary tract, including cystitis and pyelocystitis. A bibliography of the literature since 1912 is appended.

A handbook on *Pitman's shorthand* by Mr. C. SIMMONDS, has been added to Pitman's series of books on common commodities and industries. It is written in the easy style appropriate to lectures, and there is hardly a question regarding the sources, the mode of manufacture, or the uses of alcohol which is not answered sufficiently to satisfy scientific and technical as well as popular readers.

## NOTES ON BOOKS.

The third quarterly installment of this year's volume of the *(Guy's Hospital Reports)*, though of the usual size, contains four papers only, two of considerable length and two quite short. In his study of the Guy's Hospital cases of chlorosis during the last thirty years Dr. J. M. H. Campbell also collects statistics from other sources showing the reality of the widespread belief that it has become much less prevalent; thus in 1916 the number of cases was less than a quarter of that in 1903. The main cause of this diminution is the improved condition of factory life and domestic service, which thus provide more opportunities for fresh air and exercise. There are many other points of interest arising out of the analysis of the cases at Guy's Hospital, and to some of these we refer in another column. Dr. G. W. Nicholson's continuation of his "Studies on tumour formation," occupying more than fifty pages, is devoted to the consideration of the heterotopic tumours, or those consisting wholly or in part of epithelium differing fundamentally in structure from that of the cells in the organs in which they have originated—for example, a duct carcinoma of the breast lined by keratinized squamous epithelium. As in his previous studies on tumour formation, the amount of research, reading, and thought devoted to this paper is remarkable, but it must be admitted that it is not exactly light reading. It provides another nail for the coffin which the author is thoughtfully constructing for Cohnheim's theory of tumours as the result of an embryonic cell-rest, or congenital malformation in its widest sense. In referring to Driesch's Gifford lectures he nearly remarks that, while this is not the place to criticize Driesch's philosophy, even were he able to do so properly, he altogether unknown in biologists, in that he knew not of the two shorter contributions that of Gordon Correll is on the beerolose tolerance test for diseases, the value of this test as claimed by H. Maclean and his co-workers is confirmed, and it is shown to indicate whether or not the liver is involved in cases of amoebiasis. The other paper, by the editor, describes hereditary familial congenital smaller type, and describes hereditary familial congenital haemorrhagic nephritis occurring in sixteen individuals in three generations.

for Youth and the Race: The Development and Education of Young Citizens taken by the National Birth Rate Commission, 1930-31. Edited by Sir James Macpherson, R.C.B.D., London: Kegan Paul, 1931. 71 pp. 1s. 6d.

pp. 378-381, 382, 383, 384, 385, 386, 387, 388, 389, 390, 391, 392, 393, 394, 395, 396, 397, 398, 399, 400, 401, 402, 403, 404, 405, 406, 407, 408, 409, 410, 411, 412, 413, 414, 415, 416, 417, 418, 419, 420, 421, 422, 423, 424, 425, 426, 427, 428, 429, 430, 431, 432, 433, 434, 435, 436, 437, 438, 439, 440, 441, 442, 443, 444, 445, 446, 447, 448, 449, 450, 451, 452, 453, 454, 455, 456, 457, 458, 459, 460, 461, 462, 463, 464, 465, 466, 467, 468, 469, 470, 471, 472, 473, 474, 475, 476, 477, 478, 479, 480, 481, 482, 483, 484, 485, 486, 487, 488, 489, 490, 491, 492, 493, 494, 495, 496, 497, 498, 499, 500, 501, 502, 503, 504, 505, 506, 507, 508, 509, 510, 511, 512, 513, 514, 515, 516, 517, 518, 519, 520, 521, 522, 523, 524, 525, 526, 527, 528, 529, 530, 531, 532, 533, 534, 535, 536, 537, 538, 539, 540, 541, 542, 543, 544, 545, 546, 547, 548, 549, 550, 551, 552, 553, 554, 555, 556, 557, 558, 559, 560, 561, 562, 563, 564, 565, 566, 567, 568, 569, 570, 571, 572, 573, 574, 575, 576, 577, 578, 579, 580, 581, 582, 583, 584, 585, 586, 587, 588, 589, 590, 591, 592, 593, 594, 595, 596, 597, 598, 599, 600, 601, 602, 603, 604, 605, 606, 607, 608, 609, 610, 611, 612, 613, 614, 615, 616, 617, 618, 619, 620, 621, 622, 623, 624, 625, 626, 627, 628, 629, 630, 631, 632, 633, 634, 635, 636, 637, 638, 639, 640, 641, 642, 643, 644, 645, 646, 647, 648, 649, 650, 651, 652, 653, 654, 655, 656, 657, 658, 659, 660, 661, 662, 663, 664, 665, 666, 667, 668, 669, 670, 671, 672, 673, 674, 675, 676, 677, 678, 679, 680, 681, 682, 683, 684, 685, 686, 687, 688, 689, 690, 691, 692, 693, 694, 695, 696, 697, 698, 699, 700, 701, 702, 703, 704, 705, 706, 707, 708, 709, 710, 711, 712, 713, 714, 715, 716, 717, 718, 719, 720, 721, 722, 723, 724, 725, 726, 727, 728, 729, 730, 731, 732, 733, 734, 735, 736, 737, 738, 739, 740, 741, 742, 743, 744, 745, 746, 747, 748, 749, 750, 751, 752, 753, 754, 755, 756, 757, 758, 759, 760, 761, 762, 763, 764, 765, 766, 767, 768, 769, 770, 771, 772, 773, 774, 775, 776, 777, 778, 779, 780, 781, 782, 783, 784, 785, 786, 787, 788, 789, 790, 791, 792, 793, 794, 795, 796, 797, 798, 799, 800, 801, 802, 803, 804, 805, 806, 807, 808, 809, 810, 811, 812, 813, 814, 815, 816, 817, 818, 819, 820, 821, 822, 823, 824, 825, 826, 827, 828, 829, 830, 831, 832, 833, 834, 835, 836, 837, 838, 839, 840, 841, 842, 843, 844, 845, 846, 847, 848, 849, 850, 851, 852, 853, 854, 855, 856, 857, 858, 859, 860, 861, 862, 863, 864, 865, 866, 867, 868, 869, 870, 871, 872, 873, 874, 875, 876, 877, 878, 879, 880, 881, 882, 883, 884, 885, 886, 887, 888, 889, 890, 891, 892, 893, 894, 895, 896, 897, 898, 899, 900, 901, 902, 903, 904, 905, 906, 907, 908, 909, 910, 911, 912, 913, 914, 915, 916, 917, 918, 919, 920, 921, 922, 923, 924, 925, 926, 927, 928, 929, 930, 931, 932, 933, 934, 935, 936, 937, 938, 939, 940, 941, 942, 943, 944, 945, 946, 947, 948, 949, 950, 951, 952, 953, 954, 955, 956, 957, 958, 959, 960, 961, 962, 963, 964, 965, 966, 967, 968, 969, 970, 971, 972, 973, 974, 975, 976, 977, 978, 979, 980, 981, 982, 983, 984, 985, 986, 987, 988, 989, 990, 991, 992, 993, 994, 995, 996, 997, 998, 999, 1000.

1911-1810 deals with the Australian Infantry Force in Sinai and Palestine, and is written by Mr. S. GULLER. It is, we understand, the second volume of the set in order of publication. O how many volumes the whole work is to consist we do not know, but it seems likely that the whole publication will certainly provide the average reader with padding for several months. But although lengthy, this official history, if the present volume be a fair sample of the whole, may well prove a popular success. One

from prolonged illness. This is the opinion I maintained and the practice I adopted until quite recently. The increasing vogue of operations designed to restore the function of closed tubes, and latter-day methods of diagnosing such closure by inflation and so forth, make the question more difficult to answer:

What we need is evidence of the value of tubes subsequent to operative reopening, and here again I am hoping that such will be forthcoming as a result of this discussion. Speaking for myself, I would say that I have performed a considerable number of these reparative operations during the last fifteen years, and the number of successes I have had—that is, the number of times pregnancy has occurred subsequent to the operation—is small. Cases with simple closure of the abdominal ostium without tubal distension are, I believe, the only ones likely to yield a fair percentage of successes. When the tube is distended both ends are closed, and no operative technique that I know of offers much chance, I think, of permanently restoring communication with the uterus—not even reimplantation; and what I have said applies also to cases where the closure affects only the uterine end as proved by inflation.

However, I am most willing—nay, most anxious—to be converted from this pessimistic view by more favourable evidence, and I hope some of the speakers will be able to give it. If it be shown, now or in the future, that tubal function lost by inflammation can be restored by surgical means in a fair percentage of patients, then the case for conservation of the tubes at the primary operation is strengthened, for the surgeon, having failed in his first endeavour to restore the reproductive organs to their normal state, would still have another bolt to shoot. Conversely, if the truth turns out to be that recovery by Nature or operative repair is a feeble hope, we shall have regretfully to fall back on removal of the tubes at the earliest possible moment as the least disastrous way out of a situation laden with disasters.

### III.—PROFESSOR W. BLAIR BELL, B.S., M.D., Gynaecological Surgeon, Royal Infirmary, Liverpool.

I CONGRATULATE Mr. Bourne on his paper, and on his attempt to deal with so disabling a condition as acute salpingitis by conservative methods. It must be conceded by all that such endeavours are almost beyond criticism, and that they are worthy of emulation. I have often insisted that in gynaecological surgery the limit has long ago been reached in regard to eradication, and that the perfection of conservative procedures alone remains as an ideal of the scientific surgeon.

The method of treatment advocated by Mr. Bourne is the same as that described by Holden<sup>1</sup> two years ago for "chronic adnexal disease," except in regard to minor details, such as the suture of one lip of the incision to the round ligament, which was suggested by Holden in order that intestinal adhesions may be avoided. It is true that Holden practises the operation for chronic lesions, whereas Mr. Bourne employs this procedure in acute infections.

The after-histories of Holden's cases are not encouraging, for reasons that I will explain—reasons which, I think, affect, but perhaps in a less definite way, cases treated in the acute stage.

Mr. Bourne, like Holden, has not made a clear distinction between the elective lesions—if this term may be used—of the gonococcus and the streptococcus respectively; nor is the relative virulence of these organisms emphasized, except in so far as Mr. Bourne has alluded to what he calls "puerperal salpingitis" as being more serious than the non-puerperal variety. The former is, of course, usually associated with streptococcal infection, the latter with gonorrhoeal. These two infections overshadow all other infections, and presumably it is to these that Mr. Bourne refers, because such treatment as that recommended would not be applied to acute tuberculous salpingitis.

I believe that recognition of the differences in the circumstances of infection, in the essential pathology, in the aim of treatment, and in the time for operation leads to

the complete separation of the two conditions—gonorrhoeal and streptococcal salpingitis. There is, I have been glad to notice, evidence of hesitation on the part of Mr. Bourne to put his cases of "puerperal salpingitis" alongside those of "non-puerperal salpingitis." Mr. Bourne is learning by experience what others have already learned—namely, that extensive interference in acute streptococcal lesions is so dangerous, and the mortality is so high, that it is to be avoided rather than advocated.

I believe and teach: (1) That whereas the gonococcus remains localized for a long time in the mucosa of the tube, and in time may lead to the destruction of it with the formation of granulation tissue; the streptococcus, on the other hand, has a faculty for passing rapidly through the lining membrane, without permanently injuring it in a majority of cases, and reaching the lymphatics. In consequence the tube often recovers entirely or to such an extent that a salpingostomy is not required until the acute stage has long subsided. (2) That operation during the acute stage or even subacute stage of streptococcal infection is dangerous. In order to learn when operation in such cases is safe, I myself employ what I call the "chronicity test"—namely, the observation of febrile reaction or immunity after repeated examination. Any rise of temperature in such circumstances indicates that operation should be postponed. Leucocytosis, I think, is not always a sufficiently definite indication. I would remind Mr. Bourne that the streptococcus remains alive and active in the pelvic organs for many months.

In acute salpingitis in which there is a febrile reaction, and in which the presence of pus in the pelvis demands interference, I limit operative procedures to posterior colpotomy. I would therefore—as I think Mr. Bourne also shows an inclination to do—rule out the operation under the discussion as either unnecessary or too dangerous in the presence of an active streptococcal infection.

With regard to pure gonococcal infection the case is different; there is little danger to life, and in this condition I think the operation may be tried, although I have no great confidence, I am sorry to say, in approximately satisfactory results.

Undoubtedly some mild cases of gonorrhoeal salpingitis recover spontaneously. In most cases it does not appear to me likely, for the reasons given, that a cure will be effected by the operation in question, since the interstitial portion of the tube will generally be occluded. Moreover, I doubt whether incision of the tube will lead to the disappearance of the organisms located in the mucosa which is a site of election.

Mr. Bourne speaks of performing salpingectomy to save the ovary from infection. This requires great judgement, for if a tube be enlarged and adherent it is extremely difficult to remove it without damaging the blood supply to the ovary. In such circumstances, when pregnancy is impossible, I perform ovarian grafting.

Mr. Bourne's paper is most stimulating, and I think everyone must wish that success along these lines were more probable than it appears to me to be.

### IV.—LEONARD PHILLIPS, M.S., M.B., F.R.C.S., Obstetric Tutor, St. Mary's Hospital; Obstetric Surgeon to Out-patients, Queen Charlotte's Lying-in Hospital.

#### THE CONCEPTIONAL VALUE OF RECONSTRUCTED TUBES.

THE following contribution is in support of the view that the tubes should be conserved in acute salpingitis. Whether this is secured by non-interference and medical treatment, or whether by incision and drainage of the tubes, the essential consideration is that the tubes should not be sacrificed. Although they are damaged by acute salpingitis they still have a real conceptional value. The closed ostial end can be reopened, the kinked and stenosed lumen re-canalized, and the patency of the tubes once more established. In the last two years I have performed twenty-five laparotomies on women who had suffered from salpingitis in the past. In every case lesions indicating past salpingitis, and sufficient to cause sterility, were discovered. Reconstructive operations were performed in 20 cases, and

<sup>1</sup> Holden, F. C.: *Trans. Amer. Gynecol. Soc.*, 1921, xlii, 276.

In some mild streptococcal or mixed infections, when the tube is separated from its adhesion, it is found that the fimbriae are raw and bleeding but still visible, or else are able to be everted by pressure. In these cases it is wise to ligature all bleeding points with fine catgut and to pass one or more thick strands of catgut through the ostium into the tube, but this is not essential in gonococcal cases with club-ended tubes. If the fimbriae can be preserved there is a better chance of subsequent conception, but preservation of the fimbriae is not essential to success, as conception has been recorded after total salpingectomy, while in this series three of the successful cases were salpingostomies in closed tubes without fimbriae.

#### (b) Partial Salpingectomy.

If the ostial end of the tube is so torn or disorganized that it cannot be utilized, it can be removed and a new opening made at the free end of the remaining portion of the tube, the details of technique being similar to those already described. If much tube is sacrificed it is difficult to make a permanent opening of any size in the muscular and narrow part of the tube, and the prognosis in these cases is less favourable than in cases where the fimbriae are preserved or widely patent salpingostomies are performed. It is wiser in these cases to leave one or more strands of catgut in the tube lumen.

#### (c) Resection and Anastomosis.

If on distending the tube with air, or threading it over a needle, a definite obstruction is encountered, the affected part of the tube can be excised and the cut ends re-anastomosed.

In performing this delicate operation the mesentery in relation to the obstructed part of the tube is tied and the affected piece of the tube excised. (Diagram II, No. 1.) A fine long needle threaded with thick catgut is passed through the two portions of the tube into the uterus and

#### II. PARTIAL RESECTION AND ANASTOMOSIS OF THE TUBE.

1. The diseased or stenosed portion of the tube (A) is removed, the mesentery in relation to this area having just been tied off.
2. A strand of thick catgut is run through the tube as shown in the diagram.
- 3 and 4. The catgut is then run into the uterine cavity and out of the fundus as shown. The two ends of the catgut are tied together. 5. Then the cut ends of the tube are united by fine interrupted catgut stitches.

out through the fundus, drawing the catgut after it, the catgut at the needle end being tied to the catgut at the free end, entering the ostium of the tube. (Diagram II, Nos. 2, 3, 4, and 5.) The severed tube ends, connected now by the strand of catgut in the tube lumen, are united by a few interrupted very fine catgut sutures passed on small curved needles.

In one case (see Diagram III) with obstruction at the isthmus, the tube immediately adjacent to the uterine

cornua was excised. (Diagram III, No. 1.) The proximally cut end of the tube was then drawn into a small artificial hole in the region of the cornua. (Diagram III, Nos. 2 and 3.) This was accomplished by making a small incision in the fundus uteri, passing a curved Spencer Welch forceps through this incision into the uterine cavity and

#### III. PARTIAL RESECTION AND ANASTOMOSIS OF THE TUBE.

1. The diagrams illustrate a method of partial resection and repair of the tube when the damage or disease is at the cornual end. In the above diagram the region A is excised.
2. A small incision is made in the fundus uteri at D, and a Spencer Welch forceps passed through it, so as to emerge at the cornua and seize the cut end of the tube (B).
3. The tube is drawn through the uterine wall.
4. The incision in the fundus is closed and the tube fixed by interrupted fine catgut sutures at C.

out through the artificially bored hole, then seizing the free cut end of the tube and drawing it into the uterus, maintaining the tube in position by a few fine interrupted catgut sutures at the point where it first entered the uterine wall. (Diagram III, No. 4.) In cases of plastic operations on the cornual end of the tube there is usually considerable tension at the point where the tube is sewn into the uterus, and possibly the sutures may cut out after the abdomen is closed.

#### (d) Incision and Suture.

In some cases, rather than excise a portion of tube, the stenosed region can be incised longitudinally and sewn up transversely—that is, across the line of the tube. To avoid recurrence of stenosis a piece of catgut can be left in the lumen of the tube by passing a threaded needle, eye fore-

#### IV. INCISION AND SUTURE.

1. The tube is incised at A over the area of stenosis.
2. A threaded needle is passed, eye foremost, beyond the stenosed region.
3. The incision is sewn up in the opposite direction—that is, at right angles to the line of the tube. The needle is withdrawn so as to leave a strand of catgut in the lumen, traversing the formerly stenosed portion.

most, down the tube and beyond the incised region, withdrawing the needle and leaving the catgut in situ. (See Diagram IV, Nos. 1, 2, and 3.)

#### Results.

Twenty-five cases were subjected to laparotomy and reconstructive operations were performed in 20 cases. Of the 20 cases in which a working set of reproductive organs was left, 5 pregnancies have occurred—that is, 25 per cent. of

Meetings of Branches and Divisions.

KENT BRANCH.

The annual meeting of the Kent Branch was held at Bromley on June 14th, when the President, Dr. A. TENNYSON SMITH, gave an address to the members entitled "The Kent Branch—its Past and Future."

President's Address.

The President began his address by asking the audience how many members of the Association knew when the Association itself was founded, and pointed out that both the date of foundation, in 1832, and a likeness of the Founder, Sir Charles Hastings, appeared on every number of the JOURNAL. How much the medical profession owed to its eminent founder the present-day practitioners, he suggested, probably did not realize. Dr. Tennyson Smith then traced the origin of the present Kent Branch. Originally the Association met once a year, and provision was made for Branches to be formed "for the purpose of self-government and for the wider diffusion of the benefits of the Association." In 1836 the first Branch to be formed, the East Anglian, had its origin, and in 1844 the fifth—namely, the South-Eastern Branch—came into existence. This was the immediate forerunner of the present Kent Branch. In 1846, when Surrey and Sussex were ceded to the South-Eastern Branch, the Branch Council stated that "gentlemen residing in the most remote parts of the district will be enabled by railway communications to attend the annual meetings of the Branch wherever they may be appointed to be held and return home in the course of the one day, or at least within the space of twenty-four hours." Dr. Tennyson Smith suggested that this rather put the present-day practitioner to shame, when it was considered how difficult it often was to work up a successful divisional meeting. As an instance of the enormous amount of work the medical practitioners in those early days used to accomplish, an Ashford meeting was quoted, which began at 1 p.m. and lasted without interruption until the dinner hour at the Saracen's Head! At that time keen interest was taken in medical politics; such subjects as medical reform, a vaccination bill, a registration bill, and Poor Law medical reform were among those eagerly discussed at the meetings, and resolutions were passed and petitions formulated. The President then referred to the valuable help which the Branch possessed in the form of the first minute book of the South-Eastern Branch, from the pages of which they could judge their predecessors, and also form some estimate of the enormous strides that had been made in medicine and surgery during the last eighty years. The annual meetings of the South-Eastern Branch were so successful that it soon became apparent that others were necessary, especially as the area included was very wide. In 1857, therefore, the West Kent District was formed, which had the distinction of being the first District to be recognized. The East Kent District followed in 1861, then in 1866 and 1867 East and West Surrey respectively. East and West Sussex in 1869 and 1870, and finally the North Kent District in 1896. These Districts then evolved into Divisions. When the Association was reconstituted in 1903 all members of the Association became members of the

Branch in which they resided. The South-Eastern Branch became quite unwieldy, and at the meeting at Guildford in 1913 a motion was respectfully passed to divide the Branch into three, corresponding with the three counties of Kent, Surrey, and Sussex. Thus the Kent Branch came into being. Since then, partly owing to the great war, and partly to the resignations of members who disapproved of the action of the Association in connection with the Insurance Act, the numbers had dropped. The Council might have made mistakes, but it should be recognized that the strength of the Association depended on the amount of support and loyalty it obtained from Divisions, from the Panel and Medical Committees, and from the individual members of the medical profession. The Branch was suffering at the present time not only from fewer members but from a lack of keenness. Dr. Tennyson Smith expressed a hope that he would be allowed to welcome back to the Branch former trusted members, whose wisdom and experience would be more than helpful in moulding the reconstituted Branch to its former greatness. The Branch was under the deepest debt of gratitude to the honorary secretary, Dr. Starling, not only for his work generally, but for instituting the quarterly scientific meetings which had proved so successful. The President pointed out, however, that the Branch should not depend for ever on the keenness and hard work of the secretary, and added that all members should endeavour to bring fresh life to the Branch by introducing new members. He laid emphasis on the co-operation which should exist between the Branch and Divisions, and recommended that, as the Branch Council already referred matters to the Divisions, it would be a good plan if the Divisions could reciprocate. If this were the case, he felt that the Branch Council could do more than it did at present by focusing the opinion and influence of the medical profession, not only on county matters but also on medical politics generally. The President made a suggestion with regard to divisional meetings, that instead of inviting a stranger to read a paper, greater numbers might be drawn if several members started a discussion on some subject of general interest. He also suggested that it would be very helpful if fixture cards were issued at the beginning of the year. Dr. Tennyson Smith briefly outlined the work that the Association was doing for the medical profession, and pointed out that £3.5s. was but little to pay, not only for the JOURNAL, but for the whole organization at 429, Strand. This organization was actively engaged in furthering the interests not only of the Association but of the medical profession generally. The President concluded his address by emphasizing his plea for more members and a greater keenness among the existing members.

METROPOLITAN COURTES BARONET, FIMBERT, DIVISION.  
The inaugural meeting of the new Fimbert Division was held on August 23rd.  
The following officers were elected:  
Chairman, Dr. T. W. Hicks, Vice-Chairman, Dr. W. S. Rook, Secretary and Treasurer, Dr. W. W. Jamson, Representative in Representative Body, Dr. P. A. Sprad.  
The Division model rules of organization were approved, and also the necessary resolutions regarding the ethical rules.

sources of infection were not removed adhesions would persist. How could secondary infection down the drainage channel be avoided if the infected tube were drained? The great difficulty with all gonorrhoeal infections was that at an early stage they became mixed infections, and it seemed to him that they were courting the same result in draining the tube. Again, a persistent drainage fistula might occur which was exceedingly hard to cure. At present what was wanted was proof that early operation was of more benefit than the old-fashioned medical measures. He was not yet convinced that the results of early operation were really better. It was true that pregnancy did not occur after the older methods of treatment, but was there any evidence that it occurred after the new methods? He asked for how long had drainage to be carried out, and how many cases came back later with ventral hernia.

Dr. GILMORE CURRIER (U.S.A.) then demonstrated an apparatus which was being used at the present time in America for inflating the tubes in order to discover whether or not they were sealed without the necessity of opening the abdomen. He remarked that it was interesting to note that a certain percentage of cases actually became pregnant after being tested with this apparatus, without any other measures being adopted.

Mr. LOUIS RIVETT (London) spoke with actual experience of his instrument just demonstrated. He was quite convinced that it offered an ideal means for discovering at operation whether tubal strictures were present or not. He thought that any woman otherwise condemned to sterility would take a five to one chance of becoming pregnant. He would go further than Mr. Bourne and conserve tubes which showed a few grey gangrenous patches. He did not think that the risk of setting up general peritonitis by operating in the acute stage was by any means great. Severe secondary haemorrhage from sloughing of the pedicle after a delayed operation was a very real risk which could be completely eliminated by the early conservative operation. Another point he wished to stress was that in the early cases the abdominal ostium was not closed, whereas stenosis of the uterine ostium probably was present. Witness the free leakage of pus from the abdominal ostium which otherwise would take place into the uterus.

Dr. HENDRY (Glasgow) agreed that it was very difficult to get cases in the early stages. He thought the President was asking for a criterion of pregnancy occurring after salpingitis which was very hard to fulfil: he required the abdomen to be opened to furnish the proof. He thought, too, that the dangers of expectant treatment had been much overdrawn. Perforation of the bowel, particularly in cases which did not follow abortion, was very rare. The only case of primary perforation of the bowel in a series of 500 cases collected in Glasgow occurred in a post-abortion case which had been for three months under expectant treatment outside. He thought that the difficulty in the delayed operation could be very much reduced by delaying it still longer than was usually done. The surrounding local lesions tended to clear up and leave the tubes much more freely movable. He advised that cases should be left absolutely alone until all temperature disturbances had long ceased. He thought that the excellent results of Mr. Phillips spoke more in favour of expectant treatment because there seemed to be a large number of cases which clinically were acute salpingitis which appeared to clear up spontaneously. Mr. Phillips's operations were very suitable where symptoms only of sterility remained.

The PRESIDENT thought that a great deal of valuable evidence had been forthcoming, but it was rather disappointing. The evidence as to the restoration of tubal function, whether by early operation or as the result of expectant treatment, was very small indeed. The chances of subsequent pregnancy appeared to be very small. Mr. Phillips's results held out a ray of hope, but his cases were as yet too few. He remained convinced that early operation should be the treatment of choice. The medical profession must be educated to send these cases earlier. The conceptional value of a tube treated by expectant methods was so poor that he certainly preferred early operation to delay.

Mr. BOURNE, in reply, said that the question turned upon the desirability of early operation, and, if early operation was practised, upon the proper procedure to be carried out. He said that the discussion had confirmed him in the belief in the wisdom of early operation, and the evidence of Mr. Phillips on the results of plastic operation on the chronic tube provided valuable support for the preservation of the acute suppurating tube by salpingostomy. The drainage tube should be removed after one or two days, thus preventing the formation of adhesions.

## CERTAIN OBSERVATIONS ON THE INNERVATION OF THE UTERUS.

BY

BECKWITH WHITEHOUSE, M.S.LOND., F.R.C.S.,

AND

HENRY FEATHERSTONE, M.A., M.B.CANTAB.,  
Birmingham.

THE problem of uterine innervation and the nervous mechanism controlling parturition is one which has for many years interested the physiologist, and one which is of considerable practical importance to the obstetrician.

### Historical.

In introducing this further contribution to the subject, it is necessary to refer briefly to the work of other observers, a detailed summary of which will be found in the very excellent and complete article contained in Marshall's recently published *Physiology of Reproduction*.<sup>1</sup>

As long ago as 1867 Kehrer<sup>2</sup> noted that the uterus, when severed from all its attachments, underwent contractions if kept moist at the body temperature. This observation has since been confirmed by various other workers, including ourselves.

In 1871 Sir James Simpson<sup>3</sup> found that parturition was normal in the case of sows from which he had removed the dorsal and lumbar cord, with the exception that the last foetus of the litter in each case was not delivered. In the same year Riemann<sup>4</sup> recorded an experiment in which a cat was delivered of a kitten after complete destruction of the spinal cord from the third dorsal vertebra downwards.

These experiments, coupled with Amand Routh's<sup>5</sup> observations on the course of labour in women suffering from paraplegia, prove that an intact central nervous system is not essential for the uterus to complete its physiological function.

Belief in the existence of a so-called "lumbar centre" is, however, fairly general, based on the original experiments of Serres<sup>6</sup> in 1824 and the more recent observations of Langley and Anderson in 1891 and 1895.<sup>7</sup> Langley stated that the majority of efferent nerve fibres passed to the uterus "by way of the sympathetic in the region of the fourth, fifth and sixth lumbar ganglia, and that stimulation of the second, third, fourth and fifth lumbar nerves in cats and rabbits causes pallor and contraction of the Fallopian tubes, uterus, and vagina, but that stimulation of the first and sixth lumbar nerves produces no effect."

The recent work of Cushny,<sup>8</sup> Fellner,<sup>9</sup> and Keiffer<sup>10</sup> in 1905 and 1908, tends, however, to prove that the problem is much more complex than appears on the surface. Cushny found that stimulation of the hypogastric nerve in the rabbit as a general rule produces powerful contraction whether the uterus is pregnant or not. Fellner, on the other hand, regards the hypogastric as being motor only to the circular muscle fibres of the corpus uteri and the longitudinal fibres of the cervix. It is inhibitory, in his opinion, to the longitudinal fibres of the corpus and the circular fibres of the cervix, which are controlled entirely by the "nervi erigentes." The existence of a complicated system of sympathetic ganglia and nerve trunks in the muscular wall of the uterus has been demonstrated by Keiffer of Brussels.

Our interest in the problem was stimulated by the observation, noted by us in a previous communication,<sup>11</sup> of the extraordinary power of contraction possessed by the uterus in cases of Caesarean section performed under lumbar spinal anaesthesia with tropacocaine. A detailed investigation, partly clinical and partly experimental, was instituted to ascertain if possible the cause of this increased tone and contraction of the uterine musculature. The research is still in progress, and the present paper simply records the observations noted to date, based on clinical work and animal experiment. The deductions can in no sense be

As regards the practitioners in an isolated district there is no doubt that the same considerations apply. The only difference is that the practitioners are not likely to be able to obtain the same level of training as those in a large city. This is because the number of practitioners in a large city is much larger than in an isolated district. This means that the practitioners in a large city are more likely to be able to obtain the same level of training as those in a large city. This is because the number of practitioners in a large city is much larger than in an isolated district. This means that the practitioners in a large city are more likely to be able to obtain the same level of training as those in a large city.

“A large number of the patients in Glasgow, in England, and in the various towns of Scotland, are referred to as a “relatively small grant,” but if it is of the same amount as is available for distribution in Scotland, it will prove a broken reed. It is equivalent—if we must compare £10 or £15 are useless. It is equivalent—if we must compare urban and rural practices—to adding 22 or 33 patients to an urban panel list.

fractured their incomes enough to be. But no one has attempted what a rural physician attempts to do—estimate the minimum income which a practitioner should have.

(1) That the urban practitioner's remuneration is no basis on which to settle what a rural practitioner's fee should be.

(2) If that plan is adopted, the increase in mileage grant alone will not be sufficient to meet the increase in the mileage grant.

(3) If it is decided to make a necessary increase in the mileage grant, it must be supplemented adequately by the income from practices in isolated areas.

(4) The final result, however, arrived at, must satisfy one essential—a sufficient income to enable a country practitioner to live and educate his children, while giving in return the best service that is asked of him. For all that the last implicit I cannot do better than refer to Dr. Williams-Freeman's article.

I am quite aware that these opinions and arguments must meet with destructive criticisms. They may appear to involve preferential treatment at the expense of urban practitioners; but they do not. Finally, I have not given figures showing how such opinions can be justified and carried to practical conclusions. I have raised ideas on the subject, but lack of space forbids a detailed exposition.—I am, etc.,

August 22nd.

Committee.

Insurance.

of the necessity of changes and a summary was given of the report of the Special Subcommittee on the Medical Service in London appointed by the London Insurance Committee to inquire into the grounds for the recent criticisms made by the coroner for North-East London (Dr. Edwin Smith). When the report was received by the full committee it was felt that the answer to the charges made by the coroner might be set out in two further meetings. Accordingly, as the result of its first meeting, the Subcommittee has revised its report in this direction. After reciting again the position as to medical benefit, the result of the panel system in London in bringing about beneficial changes in the medical service available for

Abel and William Appointments.

Further courses of post-graduate instruction have been arranged by the London Panel Committee with the assistance of the authorities of Guy's Hospital, to take place in the coming autumn. The courses will be held in general medicine, midwifery, and gynaecology, and in the diseases of the ear, nose, and throat. Each course will consist of ten lectures on Thursday afternoon and will probably commence on September 20th. The classes will be held simultaneously on Thursday afternoons at 4 o'clock. The fee for each course will be 25 s., payable in advance to Dr. Robert W. G. T. Farnham, the Secretary, Staple House, 51, Chancery Lane, W.C.2, and cards of admission will be issued. There will be a special instruction in the treatment of diseases by insulin and the treatment of tuberculosis by Dreyer's diaphys. Early application for inclusion in either of the above courses should be made as the numbers admitted will be limited.

The London Panel Committee has been asked by the London Insurance Committee to give its opinion on the question of insuring health lectures to insured persons. Section 60 of the National Insurance Act, 1911, empowers an insurance committee to make provision for the giving of lectures and the publication of information on questions relating to health and to arrange with the local education authorities, the universities, or other institutions for that purpose. The Panel Committee, at its health lectures to insured persons, but considered that if such lectures were to be successful it would be necessary for them to be undertaken in local areas by local practitioners, and that this should be done under the aegis of the Panel Committees, provided that the necessary funds were made available. The Committee had under its consideration a letter issued by the Hospital Saving Association which, in its view, suggested an attempt to reinstitute the old club system, and could not fail to be inimical to the interests of practitioners. Especially those in industrial districts. It was decided to draw the attention of the British Medical Association and the Medical Practitioners' Union to the matter.

LONDON PANEL COMMITTEE.

The Chairman of the Subcommittee was Mr. David Davis, Chairman of the Medical Service Subcommittee, and the other members numbered nine, of whom two (Dr. H. J. Cardale and Dr. Lauriston E. Shaw) were medical men.

the working-class population, and the machinery for hearing complaints and taking action upon them, provided to describe the coroner's structures as altogether too sweeping.

pale and the transverse diameter being diminished. The portion of the uterus intervening between the various foetuses did not diminish and no contraction of the longitudinal fibres was observed. The lumbosacral cord was next exposed, and the faradic current applied to the same, and to the third and fourth lumbar nerves at the point where they left the cord. Stimulation both of the lumbar cord and of the third and fourth lumbar nerves produced marked contraction of the uterus and vagina, the contraction apparently involving the longitudinal fibres only. A longitudinal band, extending along the convex surface of the uterus and opposite to the mesometrium, became very evident by reason of its pallor, and resembled one of the trenia of the colon. The uterus diminished in length from the Fallopian tube to the vagina. No contraction of the circular fibres, however, was evident, as shown by any diminution in the transverse diameter of the uterus at the seat of each embryonic attachment.

The observations recorded in the foregoing experiments may briefly be annotated as follows:

1. When the lumbar cord of a rabbit is narcotized, the pregnant uterus passes into tonic contraction, the contraction apparently involving the circular muscle fibres only.
2. When the spinal cord of the same animal is divided in the dorso-lumbar region, and the lumbar cord is pithed, the tonic uterine contraction persists.
3. When the dorsal cord of the same animal is pithed, the uterus remains in a condition of systole.
4. When one cornu of the uterus in the same animal is isolated by section of the vessels and nerves in the mesometrium, this cornu relaxes and exhibits rhythmical peristaltic movements. The other cornu, with undivided mesometrium, as a control, remains contracted.
5. Transverse section of a pithed rabbit at the brim of the pelvis and division of all the structures supplying the uterus at this level with the exception of the aorta and inferior vena cava do not affect the continuity of the uterine contractions.
6. The excised uterus placed in warm saline solution continues to contract rhythmically in peristaltic waves for some minutes. Each wave apparently commences at the Fallopian tube and passes towards the vagina.
7. Stimulation of the lumbar cord and certain lumbar nerves produces contraction of the pregnant uterus and the vagina, but the contraction involves the longitudinal muscle fibres only.
8. Stimulation of the hypogastric nerve in the rabbit produces contraction of the pregnant uterus, but the contraction involves the circular muscle fibres only.

These facts, which in part confirm and in part differ from the results noted by other workers, are of interest when taken in conjunction with the clinical details already noted. Other observers have relied almost entirely upon laboratory experiments for their results. In this investigation with the aid of spinal narcosis we have the advantage of checking animal experiment by direct observation upon the human uterus and vice versa.

Again, most writers, with the exception of Fellner and Cushman, have been content to regard the uterus as a whole, and to observe the effect of stimulation of various nerves on the organ without reference to the individual muscle bundles involved. We regard this as a most important aspect of the problem. Fellner, to whose work we have already referred, regarded the hypogastric nerves as "motor" for the circular bundles of the corpus uteri, and the longitudinal bundles of the cervix, but "inhibitory" for the longitudinal muscle of the corpus and the circular muscle of the cervix. The lumbar cord, by way of the nervi erigentes, is, in his opinion, motor for the longitudinal muscle of the corpus and the circular muscle of the cervix, but inhibitory for the circular bundles of the corpus and the longitudinal bundles of the cervix.

Our work confirms Fellner's views with regard to the corpus uteri, but from our experiments and observations to date we differ from him on the question of the lower uterine segment and the cervix. We think that the circular fibres of the uterus, both in corpus and cervix, are stimulated by the sympathetic system and inhibited by the lumbar cord. The longitudinal fibres, on the other hand, both corporeal and cervical, also the longitudinal muscle in the vagina in the case of the rabbit, appear to us to be stimulated by lumbar cord impulses, and inhibited by the sympathetic. In other words, local paralysis of the lumbar cord, whether permanently by trauma or temporarily by spinal narcosis, produces marked contraction of the circular muscle fibres of the uterus as a whole, owing to uncontrolled sympathetic impulses, but the expulsive power is lost owing to paralysis of the longitudinal fibres.

Similarly, weak or absent sympathetic impulses produce overaction of the longitudinal fibres and increased expulsive efforts. The tone of the uterus as a whole, however, is lost, and the organ is "flabby" owing to paralysis of the circular fibres. There is a good deal of evidence, both experimental and clinical, which indirectly tends to confirm these suggestions. To refer once more to Sir James Simpson's observations in the case of sows from which he removed the spinal cord before parturition. He observes that "the uterine contractions were sufficient to expel the foetus from the uterus, and each foetus as it came into the vagina was thence extruded by the force transmitted from the foetus behind it; but when the last foetus came into the vagina it remained there, because there was nothing to transmit the uterine expulsive force." This interesting observation is probably explained by the fact that the circular muscle fibres with the mechanical advantage were sufficient to expel all the foetuses but the last. The last could not be expelled because the mechanical advantage was lost and the longitudinal expelling fibres of the uterus were paralysed.

Brachet,<sup>12</sup> quoted by Amand Routh, records the only case in which a spinal lesion actually involved the lumbar cord. In this patient the uterus contracted, but the contractions were not sufficient to expel the child, which had to be extracted by forceps. The placenta was also removed by hand. In Routh's cases the lesion was not in the lumbar cord and the lumbar influences cannot be regarded as being eliminated.

With regard to the influences of lumbar anaesthesia on the course of normal labour, our observation is interesting, since with the patient on whom it was tried, a multipara with a fully dilated cervix, the second stage of labour occupied one and a half hours. Further, the delivery was aided by pressure upon the uterus from the abdomen. Nevertheless, the uterus appeared to be firmly contracted for the whole time, and subsequently the amount of haemorrhage after separation of the placenta was less than normal. In other words, it was the expulsive power of the uterus which was diminished by lumbar anaesthesia.

Contraction of the circular fibres of the lower uterine segment is very evident when a Caesarean section is performed under lumbar anaesthesia, and the difficulty we experienced in one case in delivering the placenta into the vagina owing to contraction of the cervix has already been noted. Probably once the cervix is fully dilated the contractile power of the muscle is diminished by local paralysis from pressure of the presenting part. At the same time, we are of opinion that the administration of a lumbar anaesthetic before full dilatation of the cervix is a procedure attended by some risk, owing to the possibility of contraction from sympathetic influences. Any subsequent dilatation must be purely mechanical, owing to the paralysis of the longitudinal or "taking up" fibres, and may be attended by severe haemorrhage from laceration of the tissues.

The mechanism involved in the normal "systole" and "diastole" of the uterus has still to be investigated. As we, in common with other observers, have noted, the uterus when severed from all its connexions undergoes rhythmical contraction and relaxation as long as it is maintained at a normal temperature. It also responds immediately to various stimuli applied—for example, tactile, heat, faradism, etc.—behaving in this respect identically with other organs composed of involuntary muscle. Keiffer's work upon the uterine ganglia and the uterine musculature has thrown light upon the problem, but many points still remain obscure.

The present position may in general terms be summarized as follows:

1. The nervous mechanism controlling the uterus is constituted by three systems: (a) local, (b) sympathetic, (c) lumbosacral autonomic.
2. The "local" system is capable of producing rhythmical uterine contractions, and is independent of the sympathetic and autonomic systems, in common with other involuntary muscle.
3. The sympathetic stimuli are motor to the circular muscle fibres and inhibitory to the longitudinal bundles.
4. The lumbar cord stimuli are motor to the longitudinal fibres and inhibitory to the circular fibres.

of cancer. Cancer itself in its early stages is almost invariably unaccompanied by pain, and is sometimes painless throughout its progress. It is one of its most insidious dangers, since it leads the patient to delay seeking medical advice. Were cancer as painful in its early stages as is tuberculosis, there would be far fewer of those pitiable cases in which the patient first seeks advice when the cancer has reached a stage beyond palliative treatment.

Early diagnosis obviously depends upon co-operation between the patient and the doctor. Medical advice should be sought at once, if a tumour or lump is found in the breast, if an ulcerated condition exists on the tongue, lip or skin which does not heal in a few days, if there is persistent hoarseness, if a mole or wart shows a tendency to grow, if blood or mucus is passed with the stools, if there is bloody or offensive discharge at other than the normal monthly periods, especially at the change of life or after it has passed. Even with the greatest care and vigilance, however, it is not possible to detect cancer in its early stages, and those who seek advice in these circumstances are taking a wise course quite apart from the cancer possibilities. An abnormality is there, and whatever it is due to, it should be treated and not nursed in secret.

7. Treatment.

If a person has not recognized that something is wrong—and such cases occur—nothing more can be said. But very many persons are aware that something is wrong, fear it may be cancer and put off consulting a doctor because they think that an operation will be necessary. Quite apart from the fact that anaesthetics and antiseptics have robbed operations of many of their terrors, and that many such cases would not be cancers at all, the chances of a patient must be better if the earlier he or she comes under treatment. Most medical authorities believe that in cancer early operation affords the best chance to the patient, although they would not feel justified in stating that all risk of recurrence is necessarily removed by operation, even if undertaken in an early stage of the disease. But there is undoubted evidence that removal by operation, though ultimately followed by recurrence, enables many people to live a comfortable life in comfort for considerable periods, while in advanced cases such removal may relieve or prevent prolonged suffering. There are many cases, moreover, in which cancerous growths have been removed once and for all, the patient has lived for years afterwards without recurrence, and has ultimately died from an entirely different cause.

Evidence is accumulating that in some varieties of cancer, in some situations, radium or x-ray treatment, or diathermy, carried out by expert medical practitioners, offers at least a good chance to the patient as surgery, without the attendant disadvantages, and in other cases it may be tried when surgery should not postpone or delay seeking competent medical advice, and, above all, should not waste time or money by trying quick remedies which at best are useless, and at worst aggravate the disease. In any condition in which cancer is suspected, immediate and decisive action is necessary. The actual prospect of length of life after measures for the removal of cancer have been taken is not a matter for dogmatizing, but without question the earlier these measures are adopted the better.

8. Local Health Authorities and Cancer Questions.

Medical officers of health, under advice irrefragably "propaganda" in relation to certain diseases by means of public notices, advertisements, broadcast lectures, lectures, cinema, and the like. The considerations set out above show how greatly cancer differs, in regard to the applicability of these methods, from a disease such as small-pox, for which there is a sure prevention to be procured, from other diseases of the infectious class, whereas individuals must be urged to take precautions for the sake of their fellows, or from diseases in which the removal of the growth and glandular tissue is the only means of cure, and in which the patient is to be treated as a patient, and not as a carrier of infection. It is not controllable, or suggested that there should be established throughout the country a public cancer service, analogous to the services for tuberculosis or venereal diseases, or that for treating acute infectious diseases. Even if such a service were considered desirable, it would be out of the question until other matters, such as the improvement of the general medical education, have been further developed. But for other public bodies concerned should not feel discouraged from individual action within the competence of these bodies from pressing in securing better facilities for diagnosis or more effective treatment of cancer in the areas or institutions under their jurisdiction. It has, for example, been suggested that local authorities, in conjunction with the local representative bodies of the medical profession, should be encouraged to take local action in these areas.

It is not contemplated that there should be established throughout the country a public cancer service, analogous to the services for tuberculosis or venereal diseases, or that for treating acute infectious diseases. Even if such a service were considered desirable, it would be out of the question until other matters, such as the improvement of the general medical education, have been further developed. But for other public bodies concerned should not feel discouraged from individual action within the competence of these bodies from pressing in securing better facilities for diagnosis or more effective treatment of cancer in the areas or institutions under their jurisdiction. It has, for example, been suggested that local authorities, in conjunction with the local representative bodies of the medical profession, should be encouraged to take local action in these areas.

profession in suitable areas (acting through a special cancer committee or otherwise), might periodically undertake a review of such questions as the following, considering in each instance whether steps could and should be taken to meet the requirements of the area and the medical profession within it, and emphasizing the help of all who are likely to be of assistance:

1. Improving the local facilities for clinical consultations and for pathological examinations.
2. Improving the local facilities for cancer treatment (operation, x-ray, or provision of x-ray and radium apparatus) and considering the adequacy of arrangements for this purpose at hospitals, local institutions, etc., which serve the area.
3. Improving the facilities for transport of patients.
4. Arranging locally for post-graduate demonstrations, lectures, or courses in cancer for medical men practising in the area.
5. Arranging locally for the education of the public.

Should such local medical consideration of cancer problems lead to applications for the assistance or co-operation of public health authorities as well as of voluntary agencies and individuals, the Minister is confident that these applications will be considered practically and sympathetically by those to whom they are addressed. The Department will be glad at any time to receive communications on the matters above outlined in cases in which it would appear that its action would be helpful or its knowledge of local progress in dealing with cancer questions might be increased.

THE HEALTH OF LONDON.

Our issue of August 4th contained a preliminary notice of Sir William Hamner's Report for 1932, and we proceed now to refer to it in more detail.

Vital Statistics.

The taking of the census, not in April, but in fine weather at a week-end in June, when many residents were out of London, led the Registrar-General to redistribute the census population of the country, with the result that instead of showing a decrease in London, as the uncorrected figures would have done, there is a slight increase—from 4,321,669 on April 3rd, 1911, to 4,324,000 on June 20th. The age constitution has changed, the balance of effect being a lowered birth rate on the one hand and a lowered infant mortality rate on the other being that whilst in London in 1911 there were 501,065 children under 10 years old, there were only 775,688 in 1921. In the population over 10, the increase has been predominantly in females, 62,506, against only 5,690 in males, the effect of the great war. The death rate of 13.5, when analysed into periods of life, shows a record low figure under 1 year of age, but, as compared with the previous year, a notable increase from 1 to 5 years due to whooping-cough and measles, and an increase also in every life period from 20 years upwards. Infant mortality has been strikingly low in the past four years, the rates being 63, 76, 81, and 79 per 1,000 births, the chief factor being reduced prevalence of diarrhoea and enteritis. In addition, deaths from prematurity and congenital defects show a remarkable fall in the past three years: a fall not attributable to low summer temperature. Sir William Hamner holds that better midwifery practice, maternity benefit, better attention to expectant and nursing mothers, decrease in drunkenness, more resort to maternity institutions, and improvement in elementary education under the Act of 1870 have all had their share in this most desirable result. In the individual London boroughs, it is surprising that Kensington had the next highest infant mortality rate to Shoreditch in 1921, and attention is called to Dr. Fenton's report for that year, in which he notes that respiratory and diarrhoeal mortality was prominent in corrected means and tenement houses; in addition, the illegitimate birth rate was high in Kensington.

Small-pox.

Passing on to the statistics of infectious diseases, the medical officer deals first with small-pox. Most of the cases occurred in a public institution where vaccination had fallen into abeyance. The total in the year, all in the latter half of it, was 63, and the type was severe, probably from the Continent, London having so far escaped the mild disease from the provinces, where it is so costly to business and commerce. Of the 63 London cases, in 5 vaccination was doubtful, there being no sign of it; 5 of the 5 died and 2 recovered. Of 14 unvaccinated 7 died and 7 recovered. Of 46 vaccinated in infancy 10 died and 36 recovered. The three shortest intervals between primary vaccination and

In passing, I may say that I am of opinion that where a fibroid tumour calls for treatment at all, it calls for surgical treatment—myomectomy in suitable cases, failing which hysterectomy—and that radiation should only be called upon to check the haemorrhage and restore the patient in preparation for surgical interference. On the contrary, where severe haemorrhage is the cardinal symptom and a small fibroid is only discovered in the course of examination under the anaesthetic, then I am of opinion that exposure to radium is the best treatment.

The technique was fully described in the paper already mentioned, and I would only emphasize the fact that all these patients are treated by radium *in utero* and not by irradiation through the abdominal wall, nor yet by radium left in the vagina; and that all are subjected to a preliminary exploratory curettage.

The youngest of these patients was 18 and the oldest 55 years; there were ten cases under the age of 26, three of whom have already been discussed. Two of the remainder, aged 18 and 19 respectively, were so blanched when seen that they were immediately brought in by ambulance for treatment, and therefore any further temporizing was contraindicated. Therefore 50 mg. of radium sulphate was placed in the uterus for twenty-four hours, so establishing amenorrhoea. One of these cases is of three months', the other of five months' duration, so their subsequent history will be of considerable interest. Whatever the history be, they will be better off than a nullipara, aged 24, whose uterus and appendages were recently shown as having been removed for uncontrollable haemorrhage. The other five of this group, aged 19, 20, 20, 22, and 23, were treated with 50 mg. of radium sulphate for varying times of five to ten hours. In four of these cases the period was reduced in length and loss to reasonable proportions; the fifth has gone abroad, and I have not yet heard from her. The remainder of these cases followed more or less the course described in the paper already mentioned.

The sole contraindication to the use of radium is acute or chronic pelvic peritonitis. Such cases are apt to exhibit curious phenomena—namely, the onset of a subacute inflammation, terminating in abscess with the formation of large inflammatory tumours. The immediate disturbances are pelvic pain, relieved on the removal of the radium, transient frequency of micturition, and occasionally somewhat prolonged anaesthetic vomiting, relieved on the removal of the radium.

The treatment is usually successful after one exposure, but in seven cases I have had to give a second exposure, three of which were imperative. One or two periods, less commonly a third, of the nature of prolonged shows, are subsequently seen. Where a second exposure is given, anaesthesia is not necessary, except in highly nervous women.

The time at my disposal being short, I must now proceed to discuss the question of how radium acts: whether upon the ovaries, the uterus, or both.

Following tradition, we seem content to accept the German view that radium acts through the ovaries, and the statement repeated from mouth to mouth that "radium acts by castration," or "radium sterilizes the patient," grows somewhat wearisome by repetition. It is, of course, true that radium produces a menopause, but a menopause without the symptoms which are usually attributable to cessation of ovarian function. The clinical evidence in favour of this statement I argued in the paper above mentioned, and time will not allow of repetition; but I may add that the results in the increased number of cases supports the view then expressed. I propose to deal with the experimental evidence in some detail.

I conducted a series of experiments upon cats, in which the conditions which obtain clinically were reproduced as nearly as possible. The experiment was performed in this way:

A pregnant horn was opened and the foetus removed. The radium (100 mg. radium sulphate) was then implanted and the uterine horn closed around it by suture. The opposite ovary was fixed at a distance of 8 cm. from the radium, and the distance

side was lightly attached to the wall of the uterine horn in which the radium was buried. The radium was removed at the end of twenty-four hours. The experiment was repeated, the animal being killed at 12, 21, and 60 days.

In all the experiments the ovary on the same side as the radium showed profound and characteristic changes, complete destruction of large and small follicles, the corpora lutea were broken up, and in the later survivals only a few of the lutein cells were recognized. In all the experiments the opposite ovary at a distance of 8 cm. from the radium showed no variation at all from the normal. The uterine horn which contained the radium showed atrophy of the endometrium, diminution in the size and number of the glands, diminution in capillaries, and later still few stroma cells and great increase in connective tissue. The only criticism levelled at the work was based on the ground that 8 cm. is an average distance between the ovary and uterine cavity, and that it was impossible to be sure that the ovary was normally situated. Since then I have conducted a further series of experiments where the ovary was fixed at a distance of 4 cm. and the animals were killed at 6, 14, 28, 35, and 49 days, the technique employed being precisely the same as before, save in the matter of the interval between the ovary and the radium. Again no microscopic change could be detected in the ovary. Now, the ovary is one of the most radio-sensitive organs, and with very limited exposures characteristic changes are observed, for which I must refer you to the Jacksonian essay.

I venture to assert that radium arrests uterine haemorrhage solely through its action on the endometrium. A prolapsed ovary lying near the uterus would be diagnosed, and, if the condition of the patient was imperative, the exposure to radium would be given with the certainty that the ovary was going to be affected, whereas any mass felt which might bear the interpretation of chronic pelvic peritonitis would be an absolute contraindication, for pelvic inflammation finally negatives the use of radium.

#### DISCUSSION.

The PRESIDENT said that such papers, founded on direct histological evidence, were of the greatest scientific value. There could be no doubt that radium, properly applied, did check uterine haemorrhage. In certain cases extremely good results had been obtained. He was glad to hear that Dr. Forsdike did not think that fibroids should be treated by radium. It was not by any means easy sometimes to determine the cause of these severe haemorrhages. Sometimes they were found to be due to fibroids so small as to be practically undiagnosable. Frequent curettage of one patient was a practice which could not be too strongly condemned. One curettage should be sufficient; multiple curettage was simply a sign of ignorance. It had been his practice in these cases of uncontrollable haemorrhage to open the abdomen, lay open the uterus, and inspect the inside carefully. Sometimes small fibroids would be found, or there might be a small polypus in one uterine cornu; sometimes there was simply a localized thickening of the endometrium. He then applied the curette through the uterine opening, and was able to do this far more thoroughly than ever it could be done through the cervix. The patient would then generally cease to menstruate altogether for from six to nine months. In the most severe cases, where the patient was critically ill, he thought the safest plan was to do a rapid subtotal hysterectomy. In this type of case in young women the uterus was often very small and ill developed, so that they might not be much the worse for losing the uterus. He was not yet satisfied that radium was to be preferred to hysterectomy in these severe cases. Radium, when properly applied, probably destroyed the endometrium completely and permanently. To remove the ovaries as well as the uterus in a young woman was nothing less than a crime. He thought that a red-hot poker, if it could be applied, would probably be as effective as radium. It might be necessary to apply radium several times. He thought repeated applications of radium carried a grave risk of recto-vaginal or vesico-vaginal fistulae, and cited some examples he had met with in his practice.

SATURDAY, SEPTEMBER 8TH, 1923.

## THE SERUM DIAGNOSIS OF SYPHILIS.

The latest of the Medical Research Council's Special Report Series gives the records of three different sets of workers who have compared the results obtained from the serological examination of serum by the Wassermann reaction and those obtained from the Sigma reaction, or flocculation test, of Dreyer and Ward. The specimens of blood were collected from the patients, divided into two equal portions, labelled with numbers, and sent to the laboratories, where the Wassermann and Sigma reactions were carried out respectively. Clinical notes were kept by those who collected the samples of blood, but those who performed the tests had no knowledge of the source of the specimens, and were quite ignorant as to whether the blood was taken from normal persons, from cases of syphilis, or from individuals suffering from other diseases. At the completion of the comparison the records of the results were sent to the Medical Research Council by both sets of workers, and subsequently the results of both series of tests were collated with the clinical notes. The outcome is a document of much interest and value.

Part I of the report—contributed by Professor G. Dreyer, Drs. H. K. Ward, J. McIntosh, and P. Fildes—gives the analysis of the results obtained in the comparison of the Wassermann and Sigma reactions in the same serum. In all 894 specimens of serum were examined, obtained from 571 individuals. From persons definitely suffering from treated or untreated syphilis 519 specimens were taken; 55 specimens were obtained from persons who had previously given a positive Wassermann reaction, although no definite evidence of syphilis was obtainable; 115 specimens were obtained from persons in whom there was a suspicion or possibility of syphilitic infection; and 203 specimens from persons suffering from other diseases, where there was neither admitted history, suspicion, nor detected signs of syphilis. The results reported showed that an approximately equal number of positive reactions were obtained by the Wassermann and Sigma tests in untreated cases of manifest syphilis, but that in treated cases the Sigma reaction gave a larger number of positive reactions than the Wassermann reaction. A rough correlation was found to exist between strong and weak reactions with each test, but the results of the two reactions, when expressed quantitatively, did not in all cases run parallel. In supposed non-syphilitic cases one or other of the reactions was positive on seven occasions. In four of these both reactions agreed, in three the Sigma reaction was positive and the Wassermann reaction negative, and in one the opposite result was recorded. A description is given in the report of the technical methods employed in the performance of the reactions. The technique of the Sigma reaction tests corresponded closely with the method previously described by Dreyer and Ward; the Wassermann reactions were performed in the opposite manner.

The Serum Diagnosis of Syphilis: the Wassermann and Sigma Reactions. Council Medical Research Council Special Report Series No. 23. H. K. Ward, J. McIntosh, and P. Fildes. 1923. 2s. 6d. net. *British Medical Journal*, June 11th, 1923, p. 653.

carried out by methods similar to those described in the Special Report Series No. 14 of the Medical Research Council. Part II of the report—contributed by Drs. Thomas Houston, S. B. Boyd Campbell, J. A. Smyth, J. C. Rankin, and Hugo Hall, working at the Royal Victoria Hospital, Belfast—gives a comparison between the results obtained by the Wassermann test (Harrison's and Fleming's methods) and the flocculation test of Dreyer and Ward. The 1,342 samples of serum examined by these methods showed complete or almost complete agreement. The divergences in the results of these examinations usually occurred in a serum with low Sigma reactions or a borderline serum. In a number of cases Sigma readings sufficiently high to warrant a diagnosis of active syphilis were found, while the other methods gave negative findings; and, on the other hand, negative Sigma reactions with a positive Wassermann occurred in a few cases. Repeated determinations on cases undergoing treatment showed a regular fall in the Sigma findings, and the Sigma readings persisted longer than positive findings by the other tests employed. The Sigma technique seldom or never gave a false positive in non-syphilitic serums, whereas the other methods occasionally did. These workers conclude that the Sigma findings seem sufficiently accurate for all clinical purposes, they correspond in a remarkable way to the intensity of the clinical features of the disease, and provide an interesting and valuable method of determining the progress of a case of syphilis under treatment, and the effect of various remedies on the course of the disease.

Part III of the report—contributed by Professor Adrian Stokes and Dr. J. T. Wigham, working at Trinity College, Dublin—gives an account of the means reaction and Sigma reaction. 1,515 reactions on identical specimens of serum from 772 individuals gave: positive with both tests, 885; negative with both tests, 571; positive Sigma, negative Wassermann, 38; positive Sigma, negative Wassermann, 21. The discrepancies thus numbered 59 in all. By analysing the evidence was obtained permitting a conclusion in 38 out of the 59 discordant results. In 25 of these the balance of evidence was in favour of the Sigma reaction and in 15 it was in favour of the Wassermann reaction. In discussing the relative merits of these two tests the authors point out that in both reactions the technique is simple, and accurate measurements are only a question of care. When large numbers of specimens have to be examined the Wassermann reaction, as usually carried out, occupies less time and is less fatiguing than the Sigma test. On the other hand, if only a small batch of serums have to be examined, the time occupied in doing the Sigma reaction is very much reduced, and time is saved by adopting the flocculation test. The Sigma method is more economical than the Wassermann method, when once the apparatus has been obtained, since no purchase and upkeep of animals is necessary. The two disadvantages of the Sigma test are that it is more laborious when large numbers of tests have to be carried out, and that more serum is necessary than for the orthodox Wassermann technique. The chief advantages of the Sigma test are (1) that only two reagents are employed instead of five, (2) that a very great amount of information may be obtained by a quantitative expression of the result, (3) that since the reagents can be standardized comparable results can be obtained by different workers.

I work with 5,200 interruptions in my gas break, with an ampérage of 6 to 7 ampères, and a steady 2 milliamperes through my Coolidge tube.

The unit skin dose is that dose which gives on the eighth day a just discernible erythema of the skin, and on the twenty-eighth day a slight pigmentation. It is 10 per cent. less than what we in England call an erythema dose. Having ascertained it for a given x-ray tube first by experiment on the human skin (preferably of the abdomen, as the skin on various parts of the body differs), all other tubes can be standardized from this one by means of an into-quantimeter. The highest homogeneity point is also ascertained by means of mathematical calculation and the use of the into-quantimeter. In the case of the Coolidge tube I have used for a large proportion of my cases I find the highest homogeneity point—that is to say, the best filtration—is 16 mm. aluminium. Therefore for convenience I use 0.5 zinc (= aluminium) + 4 aluminium.

#### *The Depth Dose.*

To ascertain what this is at a depth of, say, 10 cm., one places a wooden box containing either water, paraffin jelly, or mashed placenta in between the x-ray tube and the ionization chamber. For instance, if the electroscope of the into-quantimeter takes 14.6 seconds to discharge on the surface and 45 seconds at a depth of 10 cm., the depth dose is  $\frac{14.6 \times 100}{45} \times$  coefficient of dispersion (0.51), or 16.54 per cent. By means of Voltz's tables the depth dose can be estimated for every case, for this varies not only with the focal distance of the tube from the skin, being greater the greater the distance, but also with the size of the field, or port of entry.

#### *Sensibility Tables.*

Seitz and Wintz have worked these out. They found that 110 per cent. of the unit skin dose is necessary to destroy carcinoma cells, 80 per cent. sarcoma, and 50 per cent. tuberculous growths, whereas it requires 135 per cent. to destroy intestines and bladder, 180 per cent. to cause degenerative changes in the muscles, and 35 per cent. to destroy the Graafian follicles of the ovary. (The interstitial cells are unaffected by this dose.) All the twenty cases reported were treated with 30 to 50 per cent. of the unit skin dose at a depth of 10 cm., depending upon the individual case.

In Freiburg Gauss places the flexible cable end of the into-quantimeter either in the vagina or rectum, so measuring the number of readings until the necessary dose is reached; but I personally feel this is unjustifiably uncomfortable for the patient, especially as it seems to me to be a still more accurate method to measure the depth dose quietly in one's x-ray room when alone, and then work under precisely the same conditions—that is, the same ampérage, voltage, milliamperage, heating current, number of revolutions of the break, time of dose, and the same focal distance and filtering.

#### *Climacteric Haemorrhage.*

The exact technique I have adopted for climacteric haemorrhage is as follows: The patient is prepared just as for abdominal operation, because the contents in the intestines or bladder may cause secondary radiation, which again may cause injury to the intestinal and bladder mucous membrane. She is put lying flat on a couch and her measurements taken—circumference of abdomen, distance between anterior superior iliac spines, crests, and Baudelocque. Of course, I assume that the usual medical examination has been made—weight measured, urine tested, blood counts made, and, if necessary, a diagnostic curetting performed. If the Baudelocque measurement is less than 20 cm. we can take it that the ovaries lie at a depth of not more than 10 cm. from the skin. If more than 20 the ovary will be a little more than 10 cm., consequently an extra field will be necessary. We have to treat each ovary with 35 per cent. of a unit skin dose, using an anatomical applicator. Therefore, with a 190,000 voltage, 9 to 10 ampérage, with a 2 milliamperage in the secondary current and a Coolidge tube at a focal distance of 23 cm., a twenty-five minute skin dose,

and 17.5 per cent. depth dose, we need to give twenty-five minutes anteriorly and posteriorly to each ovary to get a 35 per cent. dose. This means a treatment of about two hours. If we are dealing with a woman under 30 years we require a 40 per cent. dose. To get this it will be sufficient to give an extra field at the side of the others, or to enlarge each field, or take a longer focal distance. In the latter cases we should have to use Voltz's tables. For instance, at 23 cm. a field of 6 by 8 cm. would require twenty-five minutes; but at 50 cm., which would give a very much better depth dose, the same field would require  $4.7 \times 25$ , or 117 minutes, and so on. A castration to obtain would last about two years, and, by varying the dose, we can make it last a longer or shorter time. In cases of acute gonorrhoea, salpingitis, etc., temporary castration such as this is also being done by many gynaecologists, to avoid exacerbation of symptoms prone to occur at the monthly periods.

#### *Fibroids of Uterus.*

The technique for fibroid tumours of the uterus is very much like that for climacteric haemorrhages. If the fibroid is no bigger than a four months' pregnancy exactly the same technique is used. If the fibroid is large and the ovaries are consequently very deep-seated and difficult to localize, it is best to give one very large field (20 by 20 cm.) anteriorly, and another posteriorly. This will involve a bigger focal distance and a very much longer time, calculated by Voltz's tables. Although interstitial fibroids react best, subserous ones are also well treated by x rays.

I. According to the Frankfort school, the certain contraindications are as follows:

1. Pedunculated submucous fibroids.
  2. Uncertainty in diagnosis (for example, dermoid cyst of ovary, etc.).
  3. Complications that are causing symptoms themselves.
- II. X rays may be used:
1. In fibroids complicated with chronic pyosalpinx.
  2. In cystic softening with necrosis and suppuration (but no curetting and dilatation must be done).
  3. In cases of very large myomata, even if there are pressure symptoms.

III. There are, however, no contraindications in the following cases:

1. Pelveo-peritoneal inflammation and inflammation of the tubes.
2. Cervical myomata.
3. Big myomata with some pressure symptoms.
4. Difficulty with micturition.

All these latter cases do well. In sarcomatous growths of the uterus x-ray treatment is said to help in the diagnosis. In the case of a fibroid there is a slow reduction in the size of the tumour, whereas in the case of a sarcoma a very quick reduction takes place.

#### *ANALYSIS OF AUTHOR'S CASES TREATED BY NEW TECHNIQUE.*

*Age.*—The youngest patient was 26, the eldest 52, the average being 43.5.

*Occupation.*—Nine patients were married, 7 having children, 11 were unmarried, 3 nurses, 1 head mistress, 1 secretary, and so on.

*Symptoms.*—Due to tumour: profuse menorrhagia, 19. Metrorrhagia, 4; pressure symptoms, 2; dysmenorrhoea, 4.

*Size of Tumour.*—(a) Size of five months' pregnancy, 3. (b) Smaller than five months' pregnancy, 17.

*Kind of Fibroid.*—(1) Subperitoneal and interstitial, 4. (2) Interstitial, 11.

*Fibrosis of uterus* (with slight enlargement only), 5.

*Number of X-ray Treatments.*—The average number given was 1.45. One treatment alone should suffice, as indeed it has in 12 of my cases, although 1 have only given a 35 per cent. dose in 4 cases. Of the other cases, 3 have been treated with less than 35 per cent.; indeed, in some cases only 27 per cent., and 1 have therefore needed to give two treatments. In future I intend giving the full 35 per cent. dose in all cases so as to avoid the second treatment.

Diagnostic curettings were done in four cases.

In 8 of my cases there was no further period of haemorrhage after one treatment; 4 cases had one monthly period; 4 cases had two monthly periods after, and 2 cases had three or four after. The other 2 cases are too recent to give any report on. Roentgen sickness I have not found severe. In only one case was there sickness at the time; in three cases slight sickness some time after; one case was very sick after.

#### *Effects of Treatment.*

The effects of treatment, therefore, by this technique one can safely say are excellent. Except for the slightest pigmentation back and front there is no evidence whatever of the patient having undergone so drastic a treatment.

was from time to time chairman of various committees taking up branches of these subjects. In some cases they were formed by the Government and in others they were instituted by members of the House to encourage and stimulate policy. He was also frequently heard in debates on questions of social reform. When Mr. Bonar Law formed his Ministry Sir W. Joynson-Hicks was appointed Under Secretary at the Foreign Office, with responsibility for the Overseas Trade Department, but was quickly promoted to the office of Postmaster-General and was soon engaged in negotiations with the object of clearing the tangle over the broadcasting arrangements. On the formation of the Baldwin Ministry, the Premier asked him to become Financial Secretary to the Treasury to help him in carrying through the Budget. The transfer implied a compliment, inasmuch as Mr. Baldwin, having so many other duties, needed a very efficient Minister to act for him when he was obliged to be absent from the House. With the elevation of Mr. Neville Chamberlain to the Chancellorship of the Exchequer, Sir William was the natural choice for succession to the Ministry of Health. He had proved himself efficient in administration and a ready and capable debater. His extra-Parliamentary activities as a prominent member of so many organizations for the encouragement of temperance and the betterment of mankind, while they lay him under no suspicion of being an extremist, offer every encouragement that he will approach, with a regulated enthusiasm, the manifold problems that will now come before him.

#### ATMOSPHERIC POLLUTION.

The Meteorological Office of the Air Ministry has issued the Eighth Report of the Advisory Committee on Atmospheric Pollution for the year ending March 31st, 1932. The report deals mainly with highly technical matters, including the value and manner of use of appliances for observational and recording work, results obtained by the standard gauge, a new form of deposit gauge, a jet apparatus for the isolation and examination of atmospheric dust, besides notes on deposits obtained at Rochdale, automatic filter records, and a brief note on researches on obscurity and visibility, which has been delayed by lack of a suitable laboratory. A deputation, including a representative of the Committee, waited on the Minister of Health to urge the need for modification of the law relating to smoke emission. At the deputation a proposal was brought forward which, the Committee thinks, should go a long way towards securing a reduction of smoke. It was that "instead of penalizing conspicuous individuals for making more smoke than their neighbours, we could substitute a method of encouraging those who made less than their neighbours, in the only way in which a materialist age understands encouragement," the way being "to reduce the rates for houses that make no smoke." This proposal is supported on the ground that a system of inflicting penalties had produced little result, whereas the suggested scheme would act gradually and automatically. In that connection the question naturally arises, and not for the first time, as to whether and if so what effort is being made to prevent atmospheric pollution from the chimneys of the new dwellings that are being built all over the country under State-subsidized schemes for workmen's houses. Where such schemes are within the area of gas lighting supplies, are stores for heating by gas being provided instead of coal grates? We trust the opportunity is being seized of establishing the beginnings of a better system than has hitherto prevailed in this old country. In the section of the report dealing with the jet apparatus for detection of atmospheric

(a. net.)  
"H.M. Stationery Office: large 10s. pp. 32, with charts and diagrams.

dust, an interesting reference is made to Professor Tyndall's method, which received much attention a good many years ago, of examining respired air by a powerful beam of light from an arc lamp brought to a focus in the air by means of a lens. Tyndall concluded that the air from the depths of the lungs was dust-free, but it is now found that this was an error. The jet apparatus shows that expired air during ordinary breathing contains about 70 per cent. of the dust particles which were breathed in, and in quiet breathing the air from the depths of the lungs contains 2.5 to 7 per cent., but after deep breathing over 20 per cent., inspiration being in all cases through the nose.

#### THE PASSING OF CHLOROSIS.

Medical men approaching the period known as middle age cannot fail to have noticed the increasing rarity of chlorosis; so much has this change of type progressed that this disease, which was once so common as to account, with dyspepsia, for a large proportion of medical out-patients. That it has diminished enormously in England and in the United States of America during the last thirty years is consistently shown by Dr. J. M. Campbell in the study of the cases at Guy's Hospital and by statistics from other sources, some of which, especially those coming from Sheffield, were provided by Professor Arthur Hall. As he had information to the same effect from Paris and Vienna it is probable that the change is almost world-wide, though it may not be universal. After discussing various possible factors Dr. Campbell ascribes this disappearance mainly to the improved conditions of factory life and domestic service and the better opportunities for fresh air and exercise. Lack of food containing iron may contribute to the production of chlorosis, but is not of equal importance; and, as the curves of chlorosis and of the deaths from pulmonary tuberculosis do not correspond, insufficient diet probably does not exert a powerful influence. The Guy's cases from 1888 to 1922 are analyzed in many directions, and show a practically continuous but irregular decline, and although there may at times have been slight differences in the meaning of the designation "chlorosis," this factor can be held responsible for a very small part of the diminished incidence of the disease. It is commonly stated that the colour index in chlorosis is lower than in secondary anaemias, but at Guy's the changes in the colour index and in the size of the red cells were found to be exactly the same in these two conditions. Examination of the gastric contents in seven cases, nearly all by the fractional method, showed a tendency to increased secretion of acid, as contrasted with the generally diminished acidity in most other anaemias and the achylia of Addison's disease. Although indigestion may persist for a long time there was no evidence of any association between chlorosis and gastric ulcer. In addition to the statistics and analysis of the Guy's cases, this paper incidentally reviews much of the literature on chlorosis, and contains thoughtful suggestions on a number of points.

#### WORKMEN'S COMPENSATION IN FRANCE.

The first French analogue of the Workmen's Compensation Act was passed in 1838, and the French, with their usual logic, at once set to work to frame scales of disability applicable to accidents of all kinds. Eventually a good many literary studies of the subject appeared, and among others the first edition of the *Guide pour l'Evaluation des Incapacités* by Professor Imbert of Marseilles and two colleagues. Among the many things to whose "scrapping" the late war led were numerous conceptions as to the final or economic outcome of various injuries, and this in its

Campbell, J. M. H.: *Guy's Hosp. Rep.*, 1922, LXXIII, 257-271.

In the museum of St. Thomas's Hospital there is a specimen (1676A) of a clean transverse rupture of the inner coats of the upper part of the descending thoracic aorta leading to diffuse and extensive haemorrhage into the surrounding connective tissue. There is no macroscopic disease of the vessel, but microscopic examination revealed the presence of marked fatty degeneration of the intima. The patient, a lad aged 18, experienced acute pain in the abdomen for three days, but complained of nothing until the day of his death. When seen, four hours before death, there was nothing in the symptoms to suggest that he was seriously ill. Death was sudden and unexpected. No history of strain or injury was elicited; at the *post-mortem* examination the mediastinum was found full of extravasated blood and the left pleura contained three pints of it. That the rupture occurred in two stages is clear from the fact that, microscopically, the termination of the rent in the inner tunics is seen to be undergoing repair.

### THREE CASES OF GASTRIC CARCINOMA PRESENTING UNUSUAL FEATURES.

BY

C. E. S. JACKSON, F.R.C.S.ENG.,

SURGEON, WEST NORFOLK HOSPITAL, KING'S LYNN.

THE following cases of carcinoma of the stomach appear to be worthy of record in view of the anomalous symptoms they presented.

#### 1. Simulating Chronic Intestinal Stasis.

A man, aged 54, was sent to me for suggestions as to treatment for chronic constipation. He was a thin but muscular man, who gave a history of very severe constipation of twelve months' duration, and of failing vision for the same length of time. His appetite was good and he had only vomited twice—once three weeks before and once seven days before my examination. He had had no pain after food, no vomiting of blood, nor melaena.

On examination of his abdomen I found no distension nor tumour, nor was there any tenderness to be detected, but there was a suspicion of visible gastric peristalsis, and this was confirmed at a later examination. All further examination was negative. I referred him to an oculist, who reported early atrophy of both optic discs, and after exclusion of pituitary tumour he suggested that the condition might be due to the absorption of toxins from his stomach. A neurologist, however, put down the condition of the optic discs to early tabes dorsalis. A test meal showed the absence of free hydrochloric acid. X rays showed that there was marked dilatation and hypertrophy of the stomach, which was not completely emptied for twenty-four hours after ingestion of the bismuth meal. A diagnosis of pyloric obstruction, probably due to a healed ulcer, was made. At operation a tumour was found, involving the greater curvature near the pylorus (microscopical examination later proved it to be columnar carcinoma). The pylorus admitted the tip of the little finger easily. There were no enlarged glands to be felt, nor was there any other evidence that the growth had extended beyond the stomach. Partial gastrectomy was performed by the posterior Polya method, and the patient left hospital on the twenty-first day. His constipation immediately disappeared, he put on weight, and ten months after the operation he informs me that his vision has improved and that his condition is in all respects satisfactory.

#### 2. Simulating Gall Stones.

A man, aged 52, with the diagnosis of gall stones. He gave a history of discomfort after food for several years, but had had no real pain after food and had never vomited until six weeks before I saw him, when he was seized with agonizing pain in the right hypochondrium, with vomiting. This pain subsided, and twenty-four hours later he became slightly jaundiced. He had had two other almost exactly similar attacks before seeing me, and in every instance these attacks occurred in the evening.

On examination I found him to be a well nourished man of healthy appearance. The abdomen moved well on respiration; no tumour was felt, but there was marked tenderness over the tip of the ninth costal cartilage, and this tenderness was accentuated at the end of inspiration. At operation a well marked carcinoma of the pylorus was found. This was adherent to the neck of the gall bladder and was separated from it with some difficulty. The gall bladder contained no stones, and its wall showed no gross pathological change. Partial gastrectomy was performed by the anterior Polya method. As there was considerable oozing from the region of the neck of the gall bladder a small drain was left in for twenty-

four hours. The patient developed a slight duodenal fistula on the ninth day, which healed within a few days, and the man was discharged in a satisfactory condition on the thirty-seventh day. He has put on weight since operation, his paroxysmal attacks have disappeared, but he complains of pain in the left hypochondrium, particularly if he becomes constipated. Presumably this pain is due to pressure upon the transverse colon by the anastomosis.

#### 3. Simulating Acute Intestinal Obstruction.

A woman, aged 63, came under my care with the following history. The day before admission to hospital she suddenly became ill with acute abdominal pain, vomiting, and distension. Her doctor ordered enemata without effect, and an immediate operation was advised, but this was refused. He therefore administered morphine and next day she came under my care. She was a thin anæmic woman and looked acutely ill. She informed me that her previous health had been good, but that for the last year she had been losing weight and her appetite had become poor. She complained of intense abdominal pain, chiefly in the right hypochondrium, and she vomited half a pint of dark material during my examination. Her pulse was 100 and of fair quality. The abdomen showed extreme distension, especially in its lower half, the upper abdomen being comparatively flat. Rigidity was present in the right hypochondrium, and on deep palpation a tender tumour could be felt. This did not move on respiration, but on account of its rigidity its outline could not be felt. The stomach appeared not to be markedly dilated, but splashing was easily elicited. No gastric nor intestinal peristalsis was seen. A turpentine enema produced a large passage of flatus, the distension completely disappeared, and in twenty-four hours the patient's condition had greatly improved, and all vomiting had ceased. Forty-eight hours after admission she suddenly collapsed and died. At the *post-mortem* examination a huge carcinoma of the pyloric end of the stomach was found. The stomach was markedly dilated and was full of fresh blood, which came from the splenic artery, into which the growth had ulcerated. There was no stricture nor other lesion of the intestinal tract.

These cases illustrate the difficulty of diagnosis in many cases of gastric carcinoma, and demonstrate the importance of radiological examination of the alimentary tract in obscure cases of abdominal disease. Early diagnosis of gastric carcinoma is of paramount importance. In its early stages it is very amenable to surgical treatment, while the last stages of the condition when left without operation are, alas! often terrible to the patients and very distressing to those around them, while recurrence after gastrectomy in many cases causes death from asthenia with slight or no suffering. Carcinoma of the stomach appears to be on the increase. It is a very protean disease, and from the point of view of diagnosis the cases may be divided into three classes:

1. Those with symptoms of gastric disorder—often labelled dyspepsia or gastritis until too late.
2. Those with signs of malignant disease in which the site is not discoverable—for example, cases which are at first diagnosed as pernicious anaemia, Addison's disease, etc.
3. Anomalous cases, three of which are described above.

## Memoranda :

### MEDICAL, SURGICAL, OBSTETRICAL.

#### ANTISTREPTOCOCCUS SERUM IN ERYTHEMA NODOSUM.

ERYTHEMA NODOSUM is most commonly described as a rheumatic affection, and the treatment in the many and various books I have consulted is invariably some preparation of salicylic acid. The prognosis as regards recovery is of course good, but the usual duration is about five or six weeks and appears to be almost uninfluenced by the usual treatment; recovery is followed by prolonged convalescence in which a rather intractable anaemia is conspicuous.

About three years ago I had two cases. The first was a woman, aged 48, who had a quinsy; about a week or ten days after its commencement, and when the throat was practically well, typical erythema nodosum developed; this lasted about five or six weeks; recovery was slow and more or less uninfluenced by the usual treatment. The second was a man of 28 who had follicular tonsillitis, followed in about ten days by a typical attack of erythema nodosum. He was treated in the usual way, and recovered in about five or six weeks. In neither case was there any history of rheumatism, and in both cases convalescence was prolonged. These two cases occurred about the same time,

## COLLOIDAL GOLD TEST FOR NEURO-SYPHILIS.

*Contributions from the Peking Union Medical College*, which includes papers delivered at the ceremonies in 1921 and reports of further work carried out in 1922. Many of these have already appeared in English and American journals, and the volume that has come to us for notice is largely a collection of reprints. It is to the researchers of the Chinese workers that one is more particularly attracted in that it should show more than anything else the standard and progress of a college such as this, and we cannot but be impressed with the thoroughness of their papers, revealing, as they do, many months of painstaking investigation. Three papers by Hsien Wu on blood analysis call for special attention, for such work has already established for the author a place among the biochemists who deal with blood and its investigation. The first paper, on the separate analysis of the corpuscles and plasma, is a most interesting survey of the distribution of more particularly non-protein nitrogen in the blood tissues, and the conclusion is reached that plasma analysis should be substituted for whole-blood analysis. The second is an account of a new colorization method for the determination of the plasma proteins, and is full of experimental detail and laboratory technique. The third paper is a contribution by Dr. T. M. Li, an Associate of the College, contributes two interesting papers on this subject. The work of the European and American staffs is of interest, for untravalled opportunity exists for the study of Eastern diseases, and papers on, for example, plague problems or the parasitology of China attract special notice. The volume is a valuable summary of the year's work, and is a helpful indication that scientific medicine has already secured a foothold in China.

## COLLOIDAL GOLD TEST FOR NEURO-SYPHILIS.

[illegible]

should be begun *de novo*, and that the value of experimental findings should be examined. As is shown in the first report presented to the *Field Distemper* Council by its technical research committee (signed by its chairman, Sir William Leishman), the proposed scheme of investigation has been founded on a very broad basis, and many technical difficulties have had to be overcome. The first step will be an attempt to isolate the causal agent of the disease from specially reared puppies which have been permitted to contract distemper by contact with dogs suffering from a natural infection. Should the presence of filter-passing virus be established a whole new field of research will be opened up which will aim at the identification of the virus by modern optical methods; the determination of its resistance to temperature, light, moisture, dryness, etc.; attempts to cultivate the virus artificially; the study of immunities, natural and acquired, in animals; the study of complications and sequelae of distemper, their cause and their present treatment. In order to secure a stock of puppies free from infection and possessing no acquired immunity the stock will be bred in a compound which is being specially built in an isolated spot on the experimental farm of the Medical Research Council. The compound will be surrounded by an unclimbable fence, and inside this area special breeding kennels will be erected. The breeding and general care of the dogs will be entrusted to two trained kennel maids, who will spend practically all their time inside the compound, and so avoid the risk of carrying distemper from outside sources. A small bungalow will be erected within the compound for the accommodation of the attendants. The only regular means of entrance to the compound will be through a cleansing room built into the walls of the compound and partitioned into two parts. Persons entering the breeding compound will be required to dress themselves of their outer garments in the first room, and then proceed to the inner room, where, after bathing, they will put on special outer clothing. Similar elaborate precautions have been devised to avoid any possible infection being carried to the dogs in the feeding of the animals; the kennel maid will receive the food, which has been suitably cooked by an outside attendant, through a small service hatch, the only communication between the preparation room and inside of the compound. During the time occupied by the erection of these buildings preliminary experiments will be carried out in temporary structures which are now rapidly nearing completion. Over £3,400 has already been subscribed to meet the expenses of this research. An American committee has been formed, several members of which have been co-opted on the British Council, and the *Field Distemper* Council is well assured that at least as much money will be forthcoming for the fund from the other side of the Atlantic as from our own countrymen.

## PEKING UNION MEDICAL COLLEGE.

In 1906 six medical missions in China, English and Americans, united to establish a school of medicine in Peking and thus laid the foundation of the Peking Union Medical College. In September, 1921, new buildings were dedicated, and as a result of the interest of the Rockefeller Institute in China there is now established an extensive medical centre, magnificently equipped and ably staffed, for the founding of a system of scientific medicine in the Far East. The addresses and papers in connection with the dedication ceremonies and papers in connection with the memorial volume. We have received also Volume II of 'Addresses and Papers, Dedication Ceremonies and Medical Conference, Peking Union Medical College, 1921. New York: Trustees and Faculty of the Peking Union Medical College. (Imp. 8vo. Pp. xi+450, illustrated.)

These articles are written by Professors E. Rohde, A. Ellinger, G. Joachimoglu, and R. Gottlieb. The actions of a very large number of substances are set out. Finally, Professor H. Fühner gives a description of the pharmacological actions of the organic dyes, substances which are of importance as internal antiseptics, and have been studied chiefly from that point of view. Information as to the action of these dyes upon the host is consequently very scattered and rather difficult to obtain; hence this article is of especial value, as in it this scattered information is collected.

As we have already stated, the work will be valuable to all those engaged in pharmacological research, but from this point of view it is regrettable that the volume before us has no index. Presumably it is intended to index the work as a whole, but as it is three years since the work began to appear, and the date of its completion appears to be rather uncertain, it would have been wiser to index the volumes separately. We believe that the work was planned before the war and that its production was hindered by the war. This will account for the fact that some of the articles are not up to date. It is impossible in practice to get a whole series of monographs written and finished simultaneously, and this disadvantage is inherent in these large productions, for by the time the whole is ready many of the parts are already out of date. This is, of course, a serious argument in favour of the production of a series of separate monographs, rather than of large volumes such as that under review. Since, however, no such monographs on pharmacology exist, those interested in the experimental evidence as to the action of drugs will find Professor Heffter's handbook useful.

#### MINOR SURGERY.

THE fact that the ninth edition of WHARTON'S *Minor Surgery*\* has appeared is evidence that it has filled a useful place in surgical literature. As the title implies, the intention of the author has been to describe the various manipulations and procedures which have come to be termed minor surgery; it therefore includes descriptions of bandaging, of asepsis and antisepsis, fractures and dislocations, and such emergency operations as the ligation of the larger arteries and the minor amputations. One part is devoted to the description of "minor surgery," and it deals with a wide variety of subjects, from blood transfusion to trusses.

The section which describes bandaging is particularly good: it is an exceedingly difficult thing to write a concise yet intelligible description of how a bandage is applied, and the author has succeeded admirably. The descriptive terms of "Burton's bandage" and "Gibson's bandage" will be new to most readers in this country; they apparently figure in American methods, but they are merely slight modifications of the old-fashioned trefoil.

The author recommends that in applying a plaster-of-Paris dressing alternate layers of loose fabric and moist plaster should be applied; this is neither a neat nor a satisfactory method. "Tents" are described as rolls of conical shape employed to keep wounds open and to facilitate the escape of discharge; this is not the commonly accepted definition. With the exception, however, of certain minor details of this description, the matter is excellent, and a great variety of interesting and useful information is given.

We have been specially attracted by the section in which the author deals with transfusion of blood. This procedure is now in such general use and it is so often employed in an emergency that its inclusion in a work of this description is very proper. An excellent description is given of the process—the details of "grouping" are clearly explained, and the various methods are fully explained and illustrated. There is scope for considerable criticism, however, in regard to the description of the intravenous infusion of saline solution. Normal saline is said to contain 6 to 9 per cent. of sterilized sodium chloride. Our main objection, however, is to the benefits

which are claimed for this method of treatment; the consensus of opinion is that it has great disadvantages, and it is regrettable that gum infusions have not been mentioned.

A very useful section deals with enemata, but we are surprised that the author has omitted to describe the method of the "molasses enema." The chapters dealing with ligation of vessels and with fractures are good, though they contain nothing original. A considerable amount of information can be gained from the perusal of this volume, and we feel confident that it will continue to have a wide circulation as a compendium of minor surgical methods.

#### SPINAL PUNCTURE.

DR. BONOLA'S book on spinal puncture and the cerebro-spinal fluid\* is mainly a practical manual dealing with the operation and with the chemical, cytological, and bacteriological examination of the fluid. It also contains chapters on the anatomy of the ependyma and choroid plexuses, and on the alterations met with in the cerebro-spinal fluid in various diseases. The view that the choroid plexuses have a secretory function is supported by a histological study of the villi, which are shown to possess an epithelium differing from that of the general ependyma and containing globules which are held to be secretory products. The absorptive function of the plexuses and the experimental proofs of its existence, together with the so-called lymphatic circulation, receive due consideration.

The general technique of spinal puncture is described, with special details relative to the cervical, dorsal, and lumbar varieties, and to the difficulties incident to the operation. In the event of the fluid withdrawn containing blood, the author recommends, as a means of distinguishing the source of the latter, that the fluid be received into three test tubes; if the coloration in all three is of the same depth the haemorrhage is pathological, if it varies the haemorrhage is due to the operation. This test, however, is inapplicable if blood is present in large amount. In the chapters on the chemical, cytological, and bacteriological examination of the cerebro-spinal fluid the standard tests are given with clear directions for their application and for the preparation of the various solutions used. A chapter is given to a description of the Wassermann and Sachs-Georgi reactions, together with those of Boveri and Lange. In estimating the value of the Wassermann reaction the author states that a positive result, in the hands of an expert, obtained from the serum of a patient not suffering from an acute infection indicates syphilis, although it is not absolutely diagnostic. Carried out, however, with cerebro-spinal fluid the value of the reaction may be considered almost absolute. A negative result in this case is, however, of no value, since the reaction is often positive with the blood and negative with the cerebro-spinal fluid. Among the special applications of spinal puncture an account is given of its employment in spinal anaesthesia, in cases of cerebral tumour, and in the direct application of medicaments, more especially in tetanus and cerebro-spinal meningitis. In a final chapter descriptions are given of the changes in the cerebro-spinal fluid characterizing the various diseases of the central nervous system.

#### THE COLLECTED WORKS OF PASTEUR.

WE have already referred on more than one occasion to the fine edition of the collected works of Pasteur which is being issued under the editorship of his grandson, Dr. VALLERY-RADOT, of the Faculty of Medicine, Paris.† It is a library edition, in large octavo, and Pasteur's own text has been followed except that obvious printers' errors have been corrected. The bibliographical references have been verified and, where necessary, corrected or completed. When Pasteur published a similar paper in several periodicals each version is given or variations are indicated in footnotes.

\* *La Rachicentesi ed il liquido Cefalo-Rachidiano*. By F. Bonola. Bologna: L. Cappelli. 1922. (Sup. roy. 8vo, pp. 190. L. 12.00).  
† *Oeuvres de Pasteur*. Collected by Dr. Pasteur Vallery-Radot, Médecin des Hôpitaux de Paris. Paris: Masson et Cie. 1922. (Jésus 8vo, Tome i, pp. 480. Fr. 50. Tome ii, pp. 660. Fr. 65.)

\* *Minor Surgery, including Bandaging*. By H. R. Wharton, M.D. Ninth edition, thoroughly revised. London: Baillière, Tindall, and Cox. (Demy 8vo, pp. xii+647; 450 figures. 18s. net.)

In her book entitled *How We Resist Disease* Dr. JEAN BROADHURST of Columbia University aims at providing nurses and general students with some sound knowledge of the subject. Furthermore, she has endeavoured to deal with it in as simple language as possible, and anyone who has ever essayed a similar task must know how exceedingly difficult an undertaking it is. On the whole, she may be deemed to have succeeded, despite the profundity and wide field covered by doctrines concerning immunity and the preventive and curative practices founded thereon. The circumstance that the latter are of much practical interest to nurses and that they are described in considerable detail will probably commend the work to those for whom it is intended.

Dr. LUCIEN CHEINISSE's yearbook of treatment for 1922,<sup>16</sup> like its two predecessors, is divided into two parts, the first containing an account of new drugs and other methods of treatment arranged according to diseases and symptoms, and the second being a review of certain therapeutic methods. To facilitate reference the subjects are arranged in both parts in alphabetical order and by the provision of a full index. Dr. Cheinisse has not only a remarkably extensive knowledge of medical literature—in addition to French he quotes English, American, German, Italian, Spanish, Dutch, and Russian authorities—but he also possesses a fine critical faculty, to which, in deference to our review of the previous volume (*JOURNAL*, May 6th, 1922, p. 723), he has given much freer play than before. The little volume, therefore, is very readable, and is indispensable to those who wish to keep in touch with advance in therapeutics.

Students entering on the study of organic chemistry can choose among a considerable number of textbooks, which, however, seldom achieve the same contact with the subject that is attained in books on inorganic chemistry. The conditions that determine the progress of reactions receive too little attention; from some books the student may even receive the impression that a knowledge of structural formulae is all that is essential. In CHAMBERLAIN'S *Organic Chemistry*<sup>17</sup> there is displayed a more perfect intimacy with the real chemistry, the knowledge of which alone will enable the worker to achieve syntheses of his own devising or understand the chemical transactions realized in the realm of biology. Obviously, much of this knowledge can only be gained through practical work, for which appropriate textbooks are required; but it is none the less important that theoretical explanations of the successes and failures of practical methods should be provided. In this direction much remains to be done by authors of elementary works, and Dr. Chamberlain's effort is a step towards that goal. The volume contains all the matter usually needed in the course for a university degree. The arrangement is satisfactory, the printing is good, and there is a serviceable index.

## PREPARATIONS AND APPLIANCES.

### *An Infants' Food.*

STUDY of the diet of infants continues to stimulate commercial production. Maltose has been represented to be of exceptional value as an additional carbohydrate in the composition of artificial food. Our attention has been directed to a product from starch consisting of maltose and dextrin prepared by Messrs. Mead Johnson and Co., of Evansville, Indiana; it is sold under the name of Dextrin-Maltose and is obtainable in this country from the American Drug Supply Co., Ltd. It is put up in three forms, one being the simple product of manufacture containing about 50 per cent. of maltose, the remainder being dextrans and moisture; another consists of the same with the addition of 2 per cent. of sodium chloride; and the third contains 3 per cent. of potassium bicarbonate. Analyses made at our direction have shown that these articles agree with the composition stated on the labels and that the purity of the manufactured product is satisfactory. The proprietors inform us that they supply to medical practitioners and child-welfare institutions a number of booklets and pamphlets. These are practical and useful; they include a chart for the infant's weight, a set of cards giving directions as to dietary for infants of different ages, and a booklet called *The Bottle-fed Baby*, which is a carefully considered instruction to mothers written in easy language. This bears no advertisement and no directions for feeding are supplied with the food packages. Directions are supplied to medical attendants, who alone, we are informed, are advertised of the firm's products.

THE BATTER  
MEDICAL JOURNAL

### *A Dried Milk.*

Milkal is the trade name of a dried milk prepared by the Dried Milk Dairy Products Ltd. We understand that Messrs. J. Lyons and Co., Ltd., who are the distributors, are willing to supply sample tins on request for inspection. Milkal is stated to be produced by the spray process. A sample received by us has been examined analytically at our direction and the report returned is satisfactory. It is found that the composition agrees with that stated on the label, which represents a full-cream milk. The emulsion formed with water is devoid of aggregated particles and the fat globules are hardly less fine than those of natural milk; this is evidence that destructive heating has been avoided. A bacteriological examination has also been made which showed the sample to be clean. It was not found to contain any chemical preservative.

### *Standard Lactose.*

Erratic results in the culture reactions of bacteria and the study of their fermentative powers are not infrequently a source of perplexity and trouble to bacteriologists. They are usually to be traced to irregularity in the quality of the materials composing the culture medium. It is a necessity of prime importance in such work to use materials of the highest purity. In attention to this need the British Drug Houses (Graham Street, City Road, N.1) are engaging in the manufacture of a highly purified lactose. A specimen has been submitted to analytical examination at our direction and has been proved to possess the high degree of purity comprehended in the term "fine chemical." We do not doubt that the utilization of this article, which is sold under the denomination of Standard Lactose B.D.H., will prove to be of material advantage in bacteriological work.

### *A Laminectomy Retractor.*

Mr. C. P. G. WAKELEY, F.R.C.S. Eng. (London, W.), writes: One of the difficulties in performing laminectomy is to obtain adequate retraction of the erector spinae muscles on each side. If the muscles are peeled away on either side and a self-retaining retractor inserted, an excellent view of the laminae is obtained and troublesome haemorrhage is avoided. It was with this object in view that Messrs. J. H. Montague, of 69, New Bond Street, have made to my design the laminectomy retractor here described. It consists of two stout steel blades with wide base and tapering towards the top. The inner edges of the blades have three curved hooks which are inserted

under the erector spinae muscles when the retractor is closed. The extension of the retractor blades is manipulated by a quick travelling screw revolving in a telescopic steel tube. On rotating a wheel at the opposite end of the tube the blades will open to five inches. I have found the retractor a very useful instrument; the adjustment is good. The whole of it is heavily nickel-plated.

### *A Simplified Extension Appliance.*

Mr. WM. RUFUS HARRIS (Assistant Surgeon, Gloucester Royal Infirmary) writes: The following appliance is intended for use with a Thomas's knee or arm splint or any modification of it. It obviates the use of any weights, pulleys, or uprights, and does not pin down the patient when extension is applied to a limb.

Adhesive strapping is first applied to the limb in the ordinary way, the wooden stirrup having two holes instead of one. Through these holes a loop of strong blind cord is threaded. This loop is slipped on to the end of the extension rod A. The thumb-screw B is then turned until the required amount of extension is applied as shown by the indicator C, which is graduated into pounds. The appliance can be used in most conditions requiring extension, and is particularly useful in conjunction with Thomas's knee-splint for the transportation of cases of fractured femur. The appliance is made by the Leeds Surgical Supply Company, Ltd., Park Lane, Leeds.

Latin, but there were a few in Greek. It is interesting to know that the four English folios (all published in London) were written by Wislizenus' *Practice of Physic* (1798); Richard a *Pygme* (it was really a chimpanzee), bearing date 1699; and William Cole's *History of Plants* (1697). The French folio was Guillaume's *Œuvres* [sic] of *Chirurgie*, published in 1649. There was a little more variety among the quaterns and octavos. In English one meets with Thomas Coghnam's *Haven of Health* (1636), *The Secrets of M. Alexis of Piedmont* (London, 1558), Barrogon's *Method of Physic*, Alexander Read's *Chirurgia* (London, 1650), Pitt's *Prælectiones de Health and Life* (London, 1704), Tuppermolech's *Receptes* (Edinburgh, 1716), Paxton's *Essay concerning the Body of Man* (London, 1701), Roger Bacon's *Cure of Old Age* (1633), Manwarthage's *Treatise of the Scoury* (1669), Gapered of the *Rickles* (1651), W. Hugg's *American Physic* (London, 1672). The subjects of all these might be matched from publishers' lists to-day, and it is very modern to find books on scurvy and rickets. We should not, however, to-day expect a book to be published with the title of Harvey's *Case of a Noblemen deceased* (1685). In French are to be found Le Clerc's history of medicine (1702), Malricar's *Maladies des Femmes Grosses et Accouchées* (1675), Franc Therenin's surgical works (1669), Nicholas Lemery's lectures on chemistry (1685), Le Medecin des *Ravures* (Paris, 1674), a book on the treatment of hernias (Paris, 1678), and Masard's *Sur les Fumées* (Amsterdam, 1669). There are works in Italian too: Bacci's *del Tesoro* (Venice, 1576), the *Flagello della Pest* by Conte Castello (Messina, 1656), a lecture on podagra by Matteo Soriano (Pavimento, 1635), Mercutio's *La Commare* (1604), and the *Secreti della Signora Isabella Correse* (Venice, 1564); there were a few books in Dutch, such as Leeuwenhoek's *Outdunkingen en Outdunkingen* (Leyden, 1666). It is an interesting thing to find among Sir Robert Sibbald's books the works of another medical knight, Sir Thomas Browne of Norwich. Thus, among the books classified as miscellaneous was "Dr. Browne's [sic] *Religio Medici*," but not in an early edition (1678); the *Vulgar Errors*, however, is represented by the first (folio) edition of 1616 (it sold for 2s.). In the same section is Burton's *Anatomy of Melancholy* in the fifth edition (1638), surely the most medical work ever written by one who was not himself a medical man; it seems to have fetched the modest sum of 1s. 5d. at the sale. As one turns over the pages of this 1723 catalogue and as so many which are now unknown are not but reflected on the exceeding transitoriness of the fame which was theirs and Regardant (1697, 1688); he had also the quarto edition of *Puritate Lost* (1669, 1688); he had Gavin Douglas's *Virgil* (1553), a Boethius of 1493, Du Bartas's "weeks" both in French and in Sylvestre's strange English verse, Spenser's [sic] *Fairy Queen*, Dryden's *Juvenal* (1713), Sir Thomas More's *Utopia* (1664), Boccaccio's *Decamerone*, Tasso's *Gerusalemme Liberata* (1582), Rabelais's *Works* Englished, Don Quixote (in French), Montaigne's *Essais* (1617), Geoffrey Chaucer's *Works* (1561), and Dryden's *Poliochion* (1613); and he was far in advance of many of his time in the possession of "Poema di Dante" (1613). In his library, therefore, there were lodged well as in medicine and surgery. Further, he was no mere author and an interest in the contents of the volumes which stood in his case far above those of the ordinary bibliophile upon the Earl of Perth, he says:

"I, by his order, acquainted him with the curious books, especially pieces of divinity, history, poems, memoirs of ministers of state, and discoveries in philosophy . . . few weeks passed without letters, either when he was in England or here" (it would have been good fortune if these had been preserved). "He not only

wrote an excellent style of English, but upon occasion made verse, and translated some psalms of Buchanan, and some odes of Horace."

From his memoirs and his library it is possible to get a not inexact picture of Sir Robert Sibbald as the learned physician, the scientist, the man of affairs, and the lover of belles lettres, and so to reconstruct a portrait of him and his work which is both inspiring and pleasing.

J. W. B.

OF PHYSICIANS AND BEARDS.

In these clean-shaven days, when rude remarks are slanted in the streets at bearded men, it is curious to turn to a little essay entitled "Wherefore Physicians affect to wear a great beard," which forms one of a collection of *Medical Discoveries upon several choice and pleasant subjects*, "written originally in Italian by the learned and famous Torredano, Englished by J. B." and printed at the Blow Bible in Bedford Street, London, in 1664. From internal evidence the translator appears to have been Joshua Baildon, who acknowledged himself as translator of an earlier volume entitled *The Ravities of the World*. For the opportunity of examining these old books we are indebted to Dr. F. J. Baildon of Southampton, who comes from the same stock as the erudite "J. B." John Francis Torredano, according to Lempriere's *Universal Biography*, was a venator of Venice, author of *A Life of Adam*, *History of the Kings of Cyprus*, some comedies, etc., collected in six volumes. He was born in 1606.

"The Beard," we read in the opening sentence, "is an ornament to the face, which adds handsomeness and vene- ration to the person. . . . From hence it is that physicians do take an especial care to have great beards." So far the author is as unwisely respectful to the medical profession as he is to *proletaria* beard. But the chance of poking a little fun at the physician was too good to miss. Might it not be that the medical beard was worn to impress the public? Torredano develops this idea with "if gravity."

"Physicians would fain make others believe that they have the skill and art to bestow health, and to prolong the thread of life in despite of fate; and therefore fearing least the approach of *illie curæ ipsum* should be cast in their teeth, there is a kind of necessity they should maintain themselves in perfect youth and a robust age, to which purpose . . . they are induced to nourish great beards, which in outward appearance makes them appear much older than they are. Or else the knowledge of their art, requiring a long and laborious study, they by a long beard would fain be thought more ancient, and by consequence more experienced. On the other hand, the explanation might be simpler and less unkind. Perhaps, after all, it was out of respect for philosophy that physicians "imparting philosophy, do consideration for the patient. The beard was a sign of sorrow or grief among the Romans."

"Who knows but that physicians willing to show themselves deeply interested in their patients' sickness and pain, do wear those long beards in token of sorrow?"

It is possible to detect in this a tincture of irony, but in his concluding passage Torredano allows a transparently generous phrase to escape him:

"The beard signifies or betokens (may add) confidence and courage. No wonder therefore that they are so much worn by physicians, who are every hour forced to combat and struggle with desperate diseases, nay with death itself."

On every page of these discourses, the author's ingenious arguments and speculations are supported by many quotations from the classics.

The preface to the volume ends with a touching appeal to the reader to overlook misprints. Although the translator continues his own introductory epistle, we have a feeling that the last sentence, at any rate, of the preface, with its English epigraph harour, may have been added by Joshua Baildon himself:

"The errors of the press which like other corruptions of this age, are very wife and spreading, are left to thy clemency for pardon. Bear with them, judicious reader, and remembering that thou art, consider how much humanity is subject to mistake."

which they run their course and in their liability to become generalized throughout the body. But they all agree in that (i) they are manifestations of disordered overgrowth of some tissue of the body, (ii) they are at first local, (iii) they are not encapsuled, (iv) they progressively invade the deeper parts, (v) they readily undergo degenerative changes, (vi) they tend to become disseminated to distant parts of the body, (vii) they lead sooner or later to the death of the individual in the vast majority of cases.

From the standpoint of preventive medicine and public health administration, there is a conspicuous contrast between cancer and groups of other morbid conditions, such as the acute infectious diseases or tuberculosis, for which the fundamental principles of prevention are well established. From the mass of medical evidence and literature on cancer, old and new, we have an extensive knowledge of its natural course and pathological anatomy; from mortality and other records we know much about its occurrence and geographical distribution. But knowledge useful for its prevention is still far from complete. The root cause or causes on which the occurrence of cancer depends remain obscure. We do not possess any specific means of producing immunity against cancer, as we have against small-pox, nor have we any specific means of curing the disease analogous to quinine for malaria or arsenobenzol compounds for syphilis. In all these directions much valuable research work has been undertaken, both within laboratories and outside them, and such research is being further pursued. Study with this object ought to receive every possible support from central and local health authorities, from those responsible for hospitals and other institutions, from voluntary agencies and from the general public.

## 2. Extent of Cancer Mortality and its Increase.

In a population of 37,885,242 persons in England and Wales in 1921, a total of 46,022 deaths were attributed to cancer. These figures imply that out of each average million persons 1,215, and out of each thousand 1,21, died of cancer. The death rate per 1,000 of the population attributed to cancer in England and Wales has gradually increased from 0.32 in 1851-60 to 1.12 in 1911-20, and 1.21 in 1921. To some extent this fourfold increase is due to the fact that a larger proportion of the population than formerly is now of those ages at which deaths from cancer commonly occur; but when full allowance has been made for this ageing of the population, the increase is from 0.33 in 1851-60 to 0.97 per 1,000 in 1911-20, and 1.01 in 1921, so that in the space of two generations the recorded mortality has trebled.

It has long been matter for discussion to what extent this increase has been due to improved diagnosis and more accurate certification of cause of death. There can be little doubt that these factors have been contributory, but unfortunately it has now to be recognized that they will not account for the whole of the recorded increase. Superficial cancers, such as those of the tongue or the female breast, were readily recognizable as such even sixty years ago, by the time death occurred. Yet in the twenty years' period 1901-21 (after making allowance for the ageing of the population) the mortality of males ascribed to cancer of the tongue has increased from 38 per million living in 1901 to 53 in 1921, and that of females from cancer of the breast from 148 in 1901 to 130 in 1921—increases of 39 and 28 per cent., respectively, in twenty years. During the same period the mortality, similarly stated, of the total population from all forms of cancer increased from 841 per million in 1901 to 1,007 in 1921, or by 20 per cent. There is only one part of the body frequently attacked by cancer, the womb, in respect of which significant increase in mortality is not recorded during these twenty years—a fact which may in some degree be attributed to the fall in the birth rate.

During this period of twenty years, from 1901 to 1921, in which cancer increased by 20 per cent., the general death rate fell by 32 per cent., that of infants by 45 per cent., and that from tuberculosis by 38 per cent., while substantial declines were recorded in respect of most other causes of mortality. An increase of mortality attributed to cancer is the common experience of modern civilization.

The frequency with which different parts of the body are attacked by fatal cancer differs greatly in different countries; it may differ over a period of years even in the same country; and changes are occurring not only in respect of the parts of the body attacked by cancer, but also in regard to the ages at which deaths occur. In this country the tendency is for deaths from cancer to occur later in life than formerly, and this change has been going on, at least amongst females, for many years. The latest available returns show that the death rate from cancer is not increasing for males up to 45 years of age, and for females up to 60. The most rapid increase is occurring in extreme old age.

Great differences in regard to the parts of the body attacked by cancer also exist between the sexes. The excess of deaths of females (over males) from cancer is entirely due to malignant disease of the breast and generative organs; in most other parts of the body a considerable excess is recorded for males. There is a great difference between the relative frequencies of different forms of cancer amongst married and single women. Cancer of the womb is more fatal to married and widowed, and cancer of the breast and ovary to single women. In 1911-20, for every 100 deaths of single women from cancer of the breast, there were 392 deaths of married women, for every 100 deaths of single women from cancer of the ovary there were only 272 deaths of married women, but for every 100 deaths from cancer of the uterus in the single women there were as many as 1,009 amongst the married women. During this period there were 463 deaths of married and widowed for every 100 deaths of single women, so the excess of deaths for the married is much larger than normal in the case of cancer of the womb, but smaller than normal in those of the breast and ovary. The

death rates for 1911-20 corrected for age distribution are not available, but for the years 1911-13 we have the following figures: distribution:—Cancer of the womb: unmarried women 123, married and widowed 293; Cancer of the breast: unmarried women 346, married and widowed 238; Cancer of the ovary: unmarried women 60, married and widowed 31.

## 3. Predisposition to Cancer.

The large majority of people go through life, even to old age, without suffering from cancer, but the geographical and social distribution of cancer mortality shows that the risk of being attacked by cancer is one which is widely disseminated. In a broad sense, liability to cancer is not an attribute of any particular social class, profession or occupation. It is to be inferred, therefore, that the occurrence of cancer depends, to an important degree, on personal predisposing factors. There would be no advantage in detailing or summarizing studies or speculations on the nature of those factors, on the specific, general or constitutional antecedents of cancer, or on the meaning of "predisposition" to cancer. Knowledge is not far enough advanced. It is right, however, to point out that hereditary predisposition to cancer has not at present been proved to be of any practical importance in man; that it cannot be asserted with scientific authority that the use of any particular article of food increases the liability to cancer, or prevents it from appearing; that no known drug or preparation will prevent its appearance or cure it when present; and that no danger of cancer has been proved to result from inhabiting houses or districts in which cancer happens to have been exceptionally common. There is no evidence to show that cancer is an infectious or contagious disease.

## 4. Chronic Irritation as a Determining Factor.

One certain fact about cancer is that it frequently follows a chronic and prolonged irritation. Not all tissues, however, are equally liable in this respect. The palm of the hand, for example, in spite of its exposure to chronic irritation of all kinds, is probably never the seat of cancer. In the female breast cancer occurs far more commonly in the deeper parts of the gland than in the nipple, which is more exposed to injury. Some tissues show a special liability to develop cancer during chronic irritation, such as the skin of the face, the lips, insides of cheeks, tongue, lower part of bowel, neck of womb. Certain varieties of chronic irritation, too, are more liable to be followed by cancer than others. Thus, in the lip, long continued irritation by a clay pipe is particularly dangerous; in the tongue, irritation by a jagged tooth or badly fitting toothplate; in the womb, the chronic ulceration which may follow confinement. Again, syphilitic disease affecting the tongue or female external generative organs, or tuberculosis of skin (lupus) affecting the face, particularly if it has necessitated prolonged treatment, is liable to end in cancer. And lastly, workers in tar, such as briquette makers, workers with anilin or paraffin, chimney sweeps, and mule-spinners are apt to suffer from cancer in special parts of the body as a consequence of repeated irritation by the particular agent concerned.

This liability of cancer to follow chronic irritation of so many different types is remarkable, and leads to the supposition that beneath them all there lies some common factor—as yet unrecognized—which is fundamental to the passage of a chronic inflammatory and non-cancerous condition into one that is definitely cancerous. In one variety of cancer (rodent ulcer) the distribution of the new growth is such that it suggests a close relationship with the nerve supply of the affected part. How far this is true and how far modifications of the body itself as distinguished from the chronic irritant play a part in the ultimate production of the cancer it is impossible to say in our present state of knowledge.

## 5. Prophylaxis.

While considerations such as those in Section 3 above show how far we are from being able to say how cancer is to be avoided; those in Section 4 indicate that there are at least some provocative causes of cancer which can be guarded against. Since cancer occurs more commonly in certain sites, it is prudent to notice and remove causes of chronic irritation in these sites. Apart altogether from cancer, people should attend to these conditions in the exercise of common care for their general health and fitness.

In this category, for example, and for reasons just given, come the removal of rough stumps of teeth or replacement of badly fitting dentures; a change of habit if pipe-smoking is found to produce soreness on the same spot of the lip or tongue; an alteration of clothing which causes irritation of particular regions of the body—for example, the breast; the avoidance of constipation and other like matters. On the same basis the possibility of establishing a chronic irritation in a region liable to cancer gives an additional reason for obtaining advice and treatment in disorders of the stomach, bowels, or womb. Finally, special precautions, the nature of which is well known to those concerned, must be adopted in certain occupations known to entail super-added and specialized risks of cancer.\*

## 6. Diagnosis of Cancer.

For reasons that are indicated in the next section early diagnosis is of the greatest importance. This means not only diagnosis of the actual existence of cancer, but, even more, diagnosis of the existence of abnormal conditions that are common precursors

\* Every medical practitioner attending on, or called in to visit, a patient whom he believes to be suffering from (a) epitheliomatous ulceration due to tar, pitch, bitumen, mineral oil, paraffin, or any compound, product or residue of any of these substances, or (b) chronic ulceration due to chronic acid or bichromate of potassium, sodium, or ammonium, or any preparation of these substances, occurring in a factory or workshop, is required to notify the case to the Chief Inspector of Factories at the Home Office.

Harrison were invited to set forth their views. Mr. Bond favoured the establishment of a Central Hospital Information Bureau for the area, with close association between central voluntary hospital and the peripheral institutions, in order to reduce the waiting lists of patients in some institutions. He thought that small but efficient out-patient clinics attached to cottage hospitals would eliminate the expense involved in attending a central institution. He suggested that cottage hospitals might make provision for convalescent patients from the central institution, and be submitted for consideration with Hospital Saturday Society in connexion with the establishment of a consultancy for the friendly societies. Mr. Campbell desired to bring the stimulus of the voluntary hospitals with a view to making modern methods of investigation and treatment available for every member of the community. Mr. Harrison looked to the use of Poor Law hospitals for the purpose of relieving the pressure on the voluntary hospitals.

The report concludes with a complaint that there is little financial recognition by insurance committees of the services of the voluntary hospitals of the area. Approximately 48 per cent. of the in-patients passing through the central voluntary hospital are insured persons. For these patients some contribution is received from approved societies. But for out-patient work, such as eye and dental treatment, the approved societies make no financial recognition at all.

#### KEEPS MATERNITY HOSPITAL.

The medical report of the Leeds Maternity Hospital for 1922 shows that during the year 2,945 maternity patients were treated—1,039 in their own homes and 1,906 in the hospital. Of the 1,906 in-patients, 1,531 were delivered at or near full term, 41 cases were admitted after delivery, 50 were cases of abortion, 1 was an ectopic gestation, and 303 were discharged undelivered. The total number of births was therefore 2,570, which is an increase of 20 from the previous year. Of the 1,906 in-patients 23 died, but this does not imply that 23 of the cases delivered in the hospital died, because 41 were cases admitted after delivery, the greater number of which were cases of puerperal sepsis. Of the 23 deaths 6 were due to puerperal sepsis, 5 to heart disease, 3 to eclampsia, 2 to pneumonia, while placenta praevia, adherent placenta and post-partum haemorrhage, albuminuria and concealed ante-partum haemorrhage, toxæmic vomiting, intestinal obstruction following Caesarean section for contracted pelvis complicated by eclampsia, pelvic peritonitis following Caesarean section, and pyelitis, accounted for one each. The standard of morbidity adopted was a rise of temperature (during the first eight days of the puerperium) exceeding 100°, occurring twice within twenty-four hours, irrespective of the pulse rate and excluding the first twenty-four hours after delivery. Of the 1,531 cases delivered in the hospital 55 were morbid (excluding abortions), which is a percentage of 3.6. Septicæmia and sapraemia were the causes of 20 of these cases of morbidity, mastitis the cause of 14, and scarlet fever the cause of 6. Of the 303 cases discharged from hospital undelivered, 246 were sent home because they were not in labour; 57 were treated for various conditions, including 14 for albuminuria, 5 for hyperteismia, and 5 for threatened miscarriage. The infantile mortality for the year, including premature children, was 246, or 15.9 per cent. The report gives interesting analyses of all the abnormal cases treated in the hospital.

#### PLAGUE AND CHOLERA SPECTERS.

The Ministry of Health has issued a circular dated August 31st, 1923, and addressed to port and riparian sanitary authorities in England and Wales, on the subject of suspected cases of plague and cholera. This states that in several recent instances the Ministry has not been informed promptly of the occurrence of suspected cases of plague on ships arriving in ports, and there has also been delay in forwarding to the Ministry for bacteriological investigation material obtained from such cases, thus causing loss of valuable time. Port and riparian sanitary authorities are reminded that under the International

## IRELAND.

### Public Economy in Northern Ireland.

The Home Ministry (Northern Ireland) has notified the Barristers' Guardians of applications for renewal of several maternity and child welfare schemes. The Home Ministry further stated that it is considered desirable to remind local authorities and others administering such schemes that in accordance with the policy of the Imperial Government, which is being followed by the Northern Government, it was determined that as far as possible no fresh commitments involving expenditure out of Government funds should be undertaken for the present. This decision applies to existing schemes as well as to proposals for new schemes. The Ministry accordingly requests that all authorities administering these schemes will exercise the utmost economy and endeavour to keep their expenditure for the current year within the limits of their expenditure for the year ended December 31st, 1921. The Guardians, after a long discussion, by a majority, voted £10 to Guilford Nursing Society.

### ORGANIZATION OF ARMY MEDICAL SERVICES.

(Irish Free State). In a recent publication of the organization of the different services and departments in the Irish Free State there is given an interesting account of the formation and rise of the Army Medical Services and the part played in their organization by the leading medical officers. It is stated that the present strength of the Medical Corps is: one major-general, who is a director of medical services, three colonels, seven commandants, twenty-five captains, seventy-nine lieutenants, eleven dentists, and twelve chemists. A badge of the badge: Antiquary Dr. Sigeron, F.R.C.P.I., and Commandant Medical Corps. It was selected and designed by the veteran McKinnney, M.D., A.M.S. The following is the description of the badge: It has been designed and is being issued to all officers in the Medical Corps. It was selected and designed by the veteran McKinnney, M.D., A.M.S. The following is the description of the badge: It consists of a silver hand inset in a bronze oval. The silver hand recalls the tradition that Neadad, Chieftain of the Tuatha de Danaan, lost his hand in the battle of South Moflura, near Cong, about 1,000 years B.C. The loss of a limb constituted a serious blemish in those days that a maimed person could not be King, and consequently Neadad had an artificial hand of silver made by the artificer, Credne Ceard, and fitted by the physician, Diaoecht, so that he might succeed to the sovereignty. For that reason he was known as "Neadad Aigeard Lamh." The bronze oval consists laterally of a staff round which a serpent is twined. The staves are joined above by a scroll containing the supererogatory motto "Comradna Legis." Below by a second scroll on which appears the motto "Ogladh na hEireann"; below by a second scroll on which appears

Belief of the Rhipured and Cripplid, there are 36,000 cripplid in New York, about 50 per cent. of whom are under 16 years of age; nearly half the cripplid are not receiving any treatment. About 3,700 of the cases have been diagnosed as due to polio-myelitis. For 3 disease, and tuberculous of the joints. According to a survey by the New York Society for the Relief of the Rhipured and Cripplid, there are 36,000 cripplid in New York, about 50 per cent. of whom are under 16 years of age; nearly half the cripplid are not receiving any treatment. About 3,700 of the cases have been diagnosed as due to polio-myelitis. For 3 disease, and tuberculous of the joints.

METROPOLITAN COUNTIES BRANCH: GREENWICH AND DEPTFORD  
DIVISION.

The annual general meeting of the Greenwich and Deptford Division was held on June 26th. The annual report was presented and approved. It was stated that three meetings of the Division and seven of the Executive Committee had been held during the year. The following subjects were dealt with: (1) The Insurance Medical Service was discussed, including the advisability or otherwise of establishing a public medical service should the terms of service under the Insurance Act for 1924 be unacceptable. (2) Representatives of the Division were co-opted on their Tuberculosis Care Committees by the boroughs of Greenwich and Deptford following a request by the Executive Committee of the Division. (3) An interesting and lucid paper by Dr. Morgan (a member of the Division) recommending the formation of a local Advisory Medical Council was fully considered. The underlying idea of having one all-inclusive medical body or committee capable of representing the various medical societies and isolated practitioners in their relations with lay bodies was held to be impracticable.

The following officers were appointed for the ensuing year:

Chairman, Dr. Beatrice F. Lovibond. Vice-Chairman, Dr. J. D. Clay. Honorary Secretary and Treasurer, Dr. Patrick Quinn. Representative in Representative Body, Rev. Dr. S. D. Bhabha.

## SOUTH MIDLAND BRANCH: BEDFORDSHIRE DIVISION.

The annual meeting of the Bedfordshire Division was held at Bedford on July 11th. Prior to the meeting the members were entertained to luncheon by the Chairman, Mr. C. I. HARMAR.

After the annual report had been adopted the following officers were elected for the ensuing year:

Chairman, Mr. W. K. Parbury. Vice-Chairman, Dr. G. T. Birks. Honorary Secretary and Treasurer, Mr. E. R. Fasnacht.

Professor LEONARD GAMGEE, surgeon to the Birmingham General Hospital, gave an instructive address entitled "Considerations on some of the clinical aspects of diseases of the gall bladder." The delivery of the address was followed by a good discussion.

## Association Notices.

## COUNCIL, 1923-24.

## VACANCIES.

NOTICE is hereby given of the following vacancies in the membership of the Council:

(i) *Indian Group*, comprising the Assam, Baluchistan, Bombay, Burma, Ceylon, Hyderabad and Central Provinces, Mesopotamia, North Bengal, Punjab, and South Indian and Madras Branches, owing to no nomination having been received at the time of the annual election.

(ii) *Canadian and West Indian Group*, comprising the Halifax (Nova Scotia), Montreal, St. John (New Brunswick), Saskatchewan, Toronto, Trinidad and Tobago, Barbados, Bermuda, British Guiana, Grenada, Jamaica, and Leeward Isles Branches, owing to no nomination having been received at the time of the annual election.

The by-laws empower the Council either to fill such vacancies itself or cause them to be filled by means of an election by the Branches concerned. The Council has decided to adopt the latter course in the present cases.

Nominations in respect of either group must be signed by not less than three members of any Branch in the group, and must be in the following form, or in one to the like effect, and should be received by the Medical Secretary not later than Saturday, October 20th, 1923:

## COUNCIL, 1923-24.

NOMINATION FORM FOR ELECTION OF A MEMBER BY THE  
GROUPED ..... BRANCHES.

By Not Less than 3 Members of the Grouped ..... Branches.

We, the undersigned, hereby nominate .....  
of ..... (Full name and address to be given)  
for election by the (Here insert the names of all the Branches in the particular Group) Branches as a member of the Council of the Association for the Session 1923-24.

Signatures and Addresses of Nominators .....  
Branch(es) .....

Date ..... 1923.

The election, if a contest occurs, will be by VOTING PAPERS, containing the names of all duly nominated Candidates, issued from the Head Office, 429, Strand, London, W.C.2, to each Member of each Branch in the Group.

ALFRED COX, Medical Secretary.

*Correction.*—In the list of members present at the meeting of the Council at Portsmouth on July 25th (SUPPLEMENT, August 11th, p. 98), Mr. A. W. Nuthall's name should have appeared.

## Insurance Correspondence.

## Remuneration of Rural Practice.

Sm,—At the Conference of Rural Practitioners held in London on July 12th last there was considerable discussion as to the most satisfactory means of ensuring that the mileage grant should be fairly distributed to the really rural practitioner.

The mileage grant originally was intended for doctors practising in mountain, moorland, and fen districts, and industrial practitioners and townsmen did not participate. Since this grant was considerably increased it was made a rule that all doctors attending panel patients at over two miles from their residence should be entitled to claim.

The result of this is that the mileage grant is no longer intended purely and simply for the rural practitioner, as I understand the term "rural." Now we have doctors in all country towns, many with considerable panel lists in and close about the town, and industrial men with large panels all round them, travelling miles into the surrounding country districts. Year by year more and more claims for mileage are being made, and I contend that in many cases it is possible an undue amount of this grant is passing from the pockets of the really rural man who most needs it into those of the men who need it least, and, as a matter of fact, are hardly entitled to it.

There are doubtless many country doctors working single-handed in sparsely populated districts whose practice is grossly encroached upon on all sides by practitioners from towns and collieries, and one can conceive some of these practices becoming derelict and not worth carrying on. My definition of a really rural doctor is a man working single-handed in a sparsely populated district, or say two men in a small country town where there is a large thinly populated country round about; and where a doctor has, say, fewer insured persons within a mile of his house than he has outside a mile or even two.

The mileage at present is paid from two miles from the doctor's residence, whether he is a really rural man or a semi-rural one, but the doctor living in a village or elsewhere in a thinly populated area does a deal of travelling within those two miles, and for which he gets no mileage. A man may have hills and dales within a mile of him. I am not thinking of my own county of Northumberland, but of what I heard at the London Conference. From what I heard there it is supremely evident that some rural practitioners in some parts of England are shockingly paid as regards mileage, considering what they do. It would seem some of these men are not clearing their travelling expenses under the Insurance Acts work.

I hold that the first claim on any mileage grant ought to be these really rural practitioners—the class of men for whom mileage was first granted at the inception of the Act. In other words, I want it seen to that the money goes to the man who most need it, and who work for it, the class of men to whom mileage is vital. To the semi-rural man mileage is a thing apart; to the ultra-rural man it is his whole existence.—I am, etc.,

Felton, Northumberland, Sept. 2nd.

ROBERT A. WELSH.

Sm,—Rural practitioners are greatly indebted to Dr. Williams-Freeman for the able manner in which he has put forward their claim for special consideration under the Insurance Act. As a rural practitioner in a scattered district, with previous considerable experience in industrial areas, I would like to put forward some arguments in furtherance of that claim.

In the first place the question is: Are these practitioners indispensable? During the war they were regarded as indispensable or placed in the last group, while endeavours to join up before called on were discountenanced. If they are indispensable they are entitled to an income adequate to the present cost of living and their social standing.

Urban practitioners do not, as a rule, know how rural practitioners live; and, I might add, do not care. That attitude is as natural as the tolerant contempt of an urban practitioner with a 2,000 panel towards a rural practitioner with 500 panel patients. For the criterion of success is not the manner of work done but the size of a panel list. Some, however, do realize our difficulties and are willing to help, but they seem to me to be going on wrong lines. In the first place a tendency often shows itself to argue, apparently on an arithmetical basis, that two rural patients are equivalent to one urban patient. There is a danger that loose statements like that may, by reiteration, be accepted as facts.

In my opinion, the remuneration of urban practitioners, of rural practitioners, and of practitioners in scattered areas are three separate and distinct problems. You cannot compare a practice having an average mileage to patients of four miles with an urban practice. Yet the urban practitioner's position

to see if savage races are likewise involved. At present no man knows the far-reaching effect of conistat infections, but it is quite certain that they are responsible for untold ills.—I am, etc.,

STANLEY PEAR, M.R.C.S., L.R.C.P.Lond.

Melbourne, July 7th.

#### INTERMEDIARY HOSTS OF SCHISTOSOMA

##### IN KYASALAND.

Sir,—I have received a letter enclosing two tubes containing specimens of five species of fresh-water molluscs from Captain W. H. Dye, R.A.M.C., medical officer, Kronga, Nyasaland, British Central Africa. He writes: "I think I can say that the enclosed specimens represent all the fresh-water molluscs to be found in this district as I have searched most thoroughly."

Captain Dye was able to infect two of the species experimentally with *Schistosoma haematobium* and *Schistosoma mansoni* respectively. The molluscs have kindly been identified as follows by Mr. G. C. Robson, Zoological Department, Natural History Museum, South Kensington.

1. *Lamella affinis* Smith (full-grown and young).
2. *Tropaea robustior* Fernald.
3. *Limnaea nativiana* Krasus.
4. *Physopsis* sp. near *sudanensis* Martens.
5. *Planorbis* sp. near *sudanensis* Martens.

Captain Dye writes of 4 (*Physopsis* sp. *globose* Morelet): "They are very common in the marshy pools, although rather difficult to find owing to their predilection for the muddy undersides of reeds, etc., and their habit of dropping off when the plant is touched. They appear to attract *S. haematobium* readily, and large numbers of miracidia disappear out of the tube in which they are put, against the control."

He goes on to describe in detail the experiments he made. He finds that the mollusc dies in two days when heavily infected with the miracidia of *S. haematobium* after taking precautions to keep the water as free from decomposition matter as possible. The experiments were repeated several times with the same results. The snails were "not killed by *S. mansoni*, but one cannot get such concentration of eggs from faeces as from urine."

In regard to 5 (*Planorbis* sp. near *sudanensis* Martens) he writes: "The one and only species of planorbis in this part of the world (I have most thoroughly searched)." This species is not killed by a heavy infection of *S. haematobium*, but they were "infected from a good heavily infected stool with *S. mansoni*."

Captain Dye sent infected snails, but they died on the journey and were too decomposed for sectioning on arrival. He appears to have discovered that *Physopsis* sp. *globose* Morelet is the intermediary host of *S. haematobium* in Nyasaland, and possibly he has also found the intermediary host for *S. mansoni* in Nyasaland (*Planorbis* sp. near *sudanensis* Martens).

The other snails which he sent had, he wrote, no attraction for either *S. haematobium* or *mansoni*.—I am, etc.,

J. B. CHRISTOPHERSON, C.B.E.,

M.D., F.R.C.P.

London, W., Sept. 1st.

#### SCHISTOSOMA INFESTATION.

Sir,—The account by Drs. Sinderson and Mills in the *British Medical Journal* for June 9th (p. 866) of recalcitrant *Schistosoma haematobium* raises several points of interest.

First, the recent recognition of cases in Palestine, Mesopotamia, and Turkish Arabia suggests the possibility of the introduction of bilharzia disease to new countries, although the thoroughness with which this disease is now being studied would account for the recognition of cases in countries where until recently it was unknown. Severe manifestations of *Schistosoma haematobium* in a comparatively early stage of the disease might suggest that the parasite has but recently been introduced on to new soil. I have noticed slight manifestations of *Schistosoma* in two patients in Natal who have never left the country. It may have been that the condition had only recently been acquired, for both of them came complaining

rather from the effects of *Schistosoma haematobium* than from the effects of *Schistosoma mansoni*. The finding of *Segmentina kantschensis* Preston at Merbank, Natal, is well which was previously known only from the Upper Nile, supports the assumption that *Schistosoma mansoni* infestation has been introduced from Egypt. Secondly, a very high eosinophilia may occur in the acute stage of bilharzia disease. In my own case it rose to 95.5 per cent. during the hepatic invasion of the flukes, but fell to 12 per cent. in the next few months without treatment. It is not common to find such high eosinophilia in chronic cases, even where the infestation is a high one; a relatively high eosinophilia may persist even after the parasites have been successfully destroyed, although it usually returns practically to normal. Thirdly, it is to be regretted that intravenous antimony could not have been employed before surgical measures were adopted in the case at Baghdad, for extensive bilharzia tissue rapidly subsides as the adult parasites and their ova are destroyed.—I am, etc.,

F. G. CAVESON, M.D.Cantab.

#### ORAL HYGIENE.

Sir,—The views of Sir John O'Connor on the use of the tooth-brush reiterated in your issue of August 25th are so diametrically opposed to the opinion and experience of the great majority of dental surgeons that they must not be allowed to pass unchallenged. Sir John states his conclusion that the cause of "dental decomposition in general"—a catalogue reminiscent of the caries, pyorrhea, gastric pollution, appendicitis, and organic decomposition in general—"is to be found in the 'insane daily scrubbing of the teeth with bristles and by the insane use of chemical dentifrices.'" Regarding "gastric pollution, appendicitis, and organic decomposition in general," whatever that may mean, I express no opinion, but the experience of thirty-five years has convinced me that the thorough and intelligent daily scrubbing of the teeth, and more particularly of the gums, and the reasonable use of a dentifrice, though this is far less important, reduces the incidence of dental caries and pyorrhea to an enormous degree; and every day my belief is strengthened by result.

Dental caries is produced by the action of fermenting food particles on the teeth, which, with the progress of civilization, have acquired an increased susceptibility to this form of attack. The debris of the soft food of the present day lodges around and between the necks of the teeth, and in the crevices of their crowns, and until the cause of the susceptibility and the means of combating it shall have been discovered, or until the diet of the people shall have been reverted to a more primitive type, thorough and careful removal of these particles with the tooth-brush remains the most efficient means of preventing caries and pyorrhea; for pyorrhea, like caries, begins as a dirt disease. Debris lodging upon the gum margin infects it and sets up a marginal gingivitis. The gum margin becomes tender, swells, and stands a little way from the tooth instead of being closely applied. This affords lodgement for more debris, while the tenderness leads to avoidance of the contact of any cleansing agent; more accumulation increases, and a vicious circle is established. Friction of the gum margin, provided by Nature when man lived on uncooked hard food, is essential to the health of teeth and gums alike; it removes the debris and stimulates the circulation in the gum margin and keeps it firm, pale, and healthy. As the cooked artificial diet of civilization no longer supplies it, it must be provided artificially. Carefully persevered with in spite of some soreness at first it will cure even a long-standing gingivitis, while it will prevent or arrest caries on all surfaces to which it is applied. For the application of this friction nothing is so good as a bristle brush, because nothing else penetrates so well between the teeth and reaches the interdental papillae, though when the gums are tender a rubber brush may be used until they are hard enough to tolerate bristles. A badger-hair brush is altogether too soft to effect this.

## ROYAL ARMY MEDICAL CORPS.

Lieut.-Colonel H. F. Shea, D.S.O., is restored to the establishment.  
Major W. W. Browne, O.B.E., relinquishes the temporary rank of Lieutenant-Colonel.  
Captains H. D. Lane, M.C., and P. Carney, M.C., retire receiving a gratuity and are granted the rank of Major.  
Captain T. P. Bulst is restored to the establishment.  
Temporary Captain R. R. Law relinquishes his commission and retains the rank of Captain.  
The following to be Lieutenants (on probation): F. J. O'Meara, W. B. F. Orr, T. W. Davidson.

## ROYAL AIR FORCE MEDICAL SERVICE.

F. K. Wilson is granted a short service commission as a Flying Officer with effect from, and with seniority of, August 8th, 1923, and is seconded for duty at the Bristol Royal Infirmary.  
Flying Officer J. D. Leahy, M.C., is granted a permanent commission.  
Flight Lieutenant A. F. Rook to R.A.F. Central Hospital, Finchley.  
Flying Officer G. Clark to R.A.F. Hospital, Cranwell.

## REGULAR ARMY RESERVE OF OFFICERS.

## ROYAL ARMY MEDICAL CORPS.

Major and Brevet Lieut.-Colonel A. J. Chambers, having attained the age limit of liability to recall, ceases to belong to the Reserve of Officers.

## INDIAN MEDICAL SERVICE.

The following Captains to be Majors: E. S. Goss, M.C., C. J. Stocker, M.C., A. W. Duncan, L. F. Brandenbourg, E. A. Penny, R. H. Candy, J. C. Bharucha, H. Hingsdon, F. J. Anderson, M.C., R. V. Morrison.

## TERRITORIAL FORCE.

## ROYAL ARMY MEDICAL CORPS.

Captain F. B. Chavasse, M.C. (late R.A.M.C.), to be Captain, with precedence as from November 1st, 1918.

## VACANCIES.

BRISTOL ROYAL INFIRMARY.—House-Surgeon to the Ear, Throat, and Nose Department. Salary £120 per annum.  
CARNEGIE DUNFERMLINE TRUST.—Assistant Medical Officer (male). Salary £550 per annum.  
CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL, Gray's Inn Road, W.C.1.—(1) Two Assistant Surgeons. (2) Three Registrars.  
CHESHIRE JOINT SANATORIUM, near Market Drayton.—Dental Surgeon.  
EAST AFRICAN MEDICAL SERVICE.—Medical Officers. Salary £600 per annum, rising to £900 with efficiency bars at £700 and £800.  
EXETER: ROYAL DEVON AND EXETER HOSPITAL.—Assistant House-Surgeon. Salary £150 per annum.  
GLOUCESTER: BARNWOOD HOUSE HOSPITAL FOR MENTAL DISORDERS.—Second Assistant Medical Officer. Salary £350 per annum.  
HALIFAX: ROYAL HALIFAX INFIRMARY.—Third House-Surgeon. Salary £150 per annum.  
LONDON COUNTY COUNCIL.—Seventh Assistant Medical Officer in the Mental Hospital Service. Salary £300 per annum, rising to £400.  
MANCHESTER: ANCOATS HOSPITAL.—(1) Resident Medical Officer. (2) Medical Registrar. Salary £200 and £100 per annum respectively.  
MAXFIELD AND DISTRICT HOSPITAL.—(1) House-Surgeon. (2) Assistant House-Surgeon. Salary £175 and £150 per annum respectively.  
QUEEN'S HOSPITAL FOR CHILDREN, Hackney Road, E.2.—House-Physician and Casualty House-Surgeon. Salary £100 per annum.  
ROYAL CHEST HOSPITAL, City Road, E.C.1.—(1) Resident Medical Officer; (2) House-Physician. Salary £200 and £120 per annum respectively.  
ROYAL EARLSWOOD ASYLUM, Redhill.—Junior Assistant Medical Officer (male). Salary £250 per annum, increasing to £280.  
ROYAL NATIONAL ORTHOPAEDIC HOSPITAL, Great Portland Street, W.1.—House-Surgeon. Salary £150 per annum.  
ROYAL NORTHERN HOSPITAL, Holloway, N.—(1) Out-Patient Medical Officer. (2) House-Surgeon. Salary at the rate of £150 and £100 per annum respectively.  
ST. PETER'S HOSPITAL FOR STONE, Henrietta Street, W.C.2.—House-Surgeon. Salary £75 per annum.  
SALFORD ROYAL.—e-Physician. (2) House-Surgeon. (3) Casually for (1) £200 per annum, for (2) £150 per annum, for (3) £150 per annum.  
SAMARITAN FREE HOSPITAL FOR WOMEN, Marylebone Road, N.W.1.—House-Surgeon. Salary £100 per annum.  
SEAFORD HOSPITAL SOCIETY, Greenwich.—House-Surgeon and House-Physician at Dreadnought Hospital. Salary at the rate of £150 per annum each and a proportion of fees.  
SHROPSHIRE ORTHOPAEDIC HOSPITAL, Gobowen, near Oswestry.—Girl Students to learn orthopaedic work. Salary, first year £16, and £20 second year.  
WEST AFRICAN MEDICAL STAFF.—Medical Officers. Salary £600 per annum, rising to £720, and if confirmed in appointment after probation £720, rising to £920.  
WEST BROMWICH AND DISTRICT HOSPITAL.—Resident Assistant House-Surgeon (male). Salary £180 per annum.  
WEST LONDON HOSPITAL, Hammersmith Road, W.6.—One House-Physician and two House-Surgeons (male). Salary at the rate of £100 per annum.  
CERTIFYING FACTORY SURGEONS.—The following vacant appointments are announced: Cerrigy-Druoidon (Denbigh), Polesworth (Warwick), Staveley (Derby), Stowmarket (Suffolk), Kirkwall (Orkney), and Maidenhead (Berks).  
MEDICAL REFERENCE.—Applications for the appointment of Medical Referee under the Workmen's Compensation Act, 1906, for the County Court Circuit No. 57 (attached more particularly to the Barnstable, Bideford, South Molton and Torrington County Courts) should reach the Private Secretary, Home Office, by September 19th.

This list of vacancies is compiled from our advertisement columns, where full particulars will be found. To ensure notice in this column advertisements must be received not later than the first post on Tuesday morning.

## APPOINTMENTS.

HALLIER, Mary, M.B., Ch.B. Leeds, Resident Medical Officer at the Semi-Convalescent Hospitals at Cookridge, Leeds General Infirmary.  
LIVELL, Eric A., M.D. Manch., Assistant Professor of Anatomy in charge of Department of Neurology, University of Toronto.  
LUND, J. R., M.R.C.S., L.R.O.P., Certifying Factory Surgeon for the St. Just District, co. Cornwall.  
MCKENZIE, Miss Ella, M.A., M.B., Ch.B. Edin., D.P.H., Woman Assistant Medical Officer of Health at Blackburn.  
STUNDERS, W. E. Roper, M.R.C.S., L.R.C.P., D.P.H., Medical Officer of Health for the Urban District of Ashby-de-la-Zouch.  
MANCHESTER ROYAL INFIRMARY.—House-Physicians: L. J. Witte, M.D., Ch.B. Manch., A. Coleman, M.D., Ch.B. Manch., A. Barlow, M.B., Ch.B. Manch., House-Surgeons: M. Parkes, M.B., Ch.B. Manch., E. J. Fouldes, M.B., Ch.B. Manch., T. Latham, M.B., Ch.B. Manch., R. Dawson, M.B., Ch.B. Manch., W. A. J. Fleming, M.B., Ch.B. Manch., House-Surgeon (Special Departments): C. J. Sharp, M.B., Ch.B. Manch., Surgical Registrar: A. G. Bryce, M.D. Manch., F.R.C.S.  
ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, Leicester Square.—Consultant Physicians: Sir Malcolm Morris, R.C.V.O., and Dr. James H. Stowers. Honorary Physicians: Wilfrid Fox, M.A., M.D., M.R.C.P., Henry MacCormac, C.B.E., M.D., F.R.C.P., Director of the Pathological Department: J. M. H. Macleod, M.D., F.R.C.P.

## British Medical Association.

OFFICES AND LIBRARY, 429, STRAND, LONDON, W.C.A.

## Reference and Lending Library.

THE READING ROOM, in which books of reference, periodicals, and standard works can be consulted, is open to members from 10 a.m. to 6.30 p.m., Saturdays 10 to 2.  
LENDING LIBRARY: Members are entitled to borrow books, including current medical works; they will be forwarded if desired, on application to the Librarian, accompanied by ls. for each volume for postage and packing.

## Departments.

SUBSCRIPTIONS and ADVERTISEMENTS (Financial Secretary and Business Manager. Telegrams: Articulate, Westrand, London).  
MEDICAL SECRETARY (Telegrams: Mediscera, Westrand, London).  
EDITOR, *British Medical Journal* (Telegrams: Altology, Westrand, London).  
Telephone number for all departments: Gerrard 2630 (3 lines).

SCOTTISH MEDICAL SECRETARY: 6, Rutland Square, Edinburgh. (Telegrams: Associate, Edinburgh. Tel.: 4561 Central.)

## POST-GRADUATE COURSES AND LECTURES.

WEST LONDON POST-GRADUATE COLLEGE, Hammersmith, W.—Mon., 12 noon, Mr. Simmonds: Applied Anatomy. Tues., 12 noon, Dr. Durrell: Chest Cases. Wed., 3 p.m., Dr. Pernet: Skin Department. Thurs., 2 p.m., Mr. MacDonald: Genito-Urinary Department. Fri., 2 p.m., Mr. Sinclair: Surgical Out-patients. Sat., 10 a.m., Dr. Paterson: Medical Diseases of Children. Daily, 10 a.m. to 6 p.m., Sat., 10 a.m. to 1 p.m., In- and Out-patients, Operations, Special Departments.

## BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 9s., which sum should be forwarded with the notice not later than the first post on Tuesday morning, in order to ensure insertion in the current issue.

## BIRTHS.

FERGUSON.—At a nursing home, Edinburgh, on Wednesday, August 22nd, the wife of W. Haig Ferguson, M.C., B.A., M.B., Ch.B., Captain R.A.M.C., of a son.  
ROPER-HALL.—On August 25th, at Llanberis House, Moseley, Birmingham, the wife of Dr. H. T. Roper-Hall, M.B., M.R.C.S., L.D.S., of a son.

## MARRIAGES.

DALLOW.—HAM.—On the 30th ult., at Wolverhampton (by special licence), John R. Dallow, M.B., Ch.B., B.Sc., of Kinner, Staffs, elder son of Mr. and Mrs. Tom Dallow, West Bromwich, to Agnes H. Ham, youngest daughter of the late Mr. and Mrs. N. Ham, Chipping Norton.  
INKSTER-COX.—At St. Alban's, Holborn, on August 27th, John Inkster, M.D., M.R.C.P., of Middlesbrough, to Olive Mary, daughter of B. H. Cox, Esq., of Toronto.  
JONES.—FRANKLIN.—At St. Mary's Church, Ajmer, India, on August 6th, 1923, by the Reverend S. P. Morris, Chaplain of Ajmer, James Walker, D.S.O., Captain, Indian Medical Service, second son of the late Sir Henry Jones, C.H., and Lady Jones, Tighnabruach, Argyllshire, to Doris Marjorie Marion, eldest daughter of Lieut.-Colonel G. D. Franklin, O.B.E., I.M.S., Chief Medical Officer in Rajputana, and the late Mrs. G. D. Franklin.

## DEATHS.

HART.—On September 1st, George Simpson Hart, M.D., of Moulton, Burton-on-Trent, aged 55.  
HILL.—On August 3rd, at a nursing home, George Hill, L.R.C.P., L.R.O.S. Edin., L.R.F.P.S. Glas. 1894, Bromfield, New Ferry, Cheshire.

[illegible]

and attack by small-pox were 14, 16, and 16 years; the three shortest intervals between primary vaccination and fatal attack were 43, 44, and 49 years, the other fatal attacks in the primarily vaccinated being at ages from 58 to 73 years. Thus every outbreak of small-pox tells in its own way the value of vaccination. In October and November over 25,000 children in the Council's schools were vaccinated. Sir William Hamer states that the London outbreak of nearly 10,000 cases, which began in 1901, cost £500,000, or about £50 a case.

#### *Tuberculosis.*

The phthisis death rate in London in 1922 was 1.08 per 1,000, made up of a 1.35 male rate and 0.84 female rate. This is a little higher than in the two immediately previous years, but lower than any of the earlier rates. It is pointed out that during the war the civil population contained practically all men suffering from phthisis, those developing phthisis in army and navy being as far as possible sent back to England, the tuberculosis mortality in the British troops in France and Belgium in 1918 being only 5 per 100,000. After reference to the age incidence of the disease, the movement of population in relation to the phthisis death rate is discussed, in continuation of what was said in the previous year's report, and in relation to Dr. Greenwood's Milroy lectures, in which he considers the influence of internal migration from country to town, contributory causes being change of diet, diminished exercise, and change of atmosphere, Dr. Bulstrode's Milroy lectures of 1903 being also noted in support of the general case.

#### *Influenza.*

The epidemic of the winter of 1921-22 was dealt with in Sir William Hamer's previous report, and this year he discusses the epidemicity of the disease since 1890, as well as the question of its varied manifestations—the scarlatiniform rash which accompanied it in London and Manchester in 1920-21, and an outbreak among students at Minnesota regarded as scarlet fever, but coincident with an epidemic of influenza. There is also mention of an epidemic of 30,000 cases of dengue at Galveston, Texas, accompanied by a toxic rash, at a time when there was also widespread influenza. Sir William Hamer is a keen epidemiologist, and sees relationships between such concurrent epidemics which would give much material for exposition of his views on the whole subject of epidemiology, if only he could find time to set it all down for the benefit of medical study in general.

#### *Enteric Fever.*

The subject of typhoid fever is dealt with at considerable length. There were in the year only 264 notified cases and 45 deaths. Of 141 cases admitted to hospital, 65 were found not to be typhoid fever. Multiple cases occurred in 14 houses, the largest number in one house being six. In 181 traced cases, shellfish is mentioned in 15, fried fish in 8, other fish in 10, watercress in 6, and other food in 33. In 25 cases contact with previous cases is mentioned. Seven nurses contracted the disease. Of the 181, 47 were not typhoid. As noted in our previous article there has been for eleven years past almost complete absence of the autumnal rise of typhoid in London. By a process of exclusion the medical officer reduces the question of origin practically to fish and shellfish. The disease has left its favoured haunts of twenty years ago. Up to 1911 certain poor areas, in a population of some half-million within the classes in question, were specially infected, multiple attacks in houses were common, and children and young adults were notably numerous among the cases. Then Sir William puts the proposition that if it be assumed that infected food was sold for many years round about the beginning of the century in this population, especially about the latter part of August and in September and in early October, and if this sale was gradually restricted in the first few years of the century, and practically discontinued about 1909 and 1912, the decline of typhoid and of its autumnal rise is largely explained. Other considerations in support of this view are submitted, and finally it is pointed out that fish has been definitely incriminated in more than a dozen outbreaks. A detailed tabulation of such occurrences is contained in the report. The question between fish and shellfish is discussed, and the latter have rather fallen out of the picture, though cockles, and especially mussels, are by no means excluded. Going back over outbreaks attributed at the time to water or milk, Sir William is inclined

to the view that in certain of them fish was probably the agency. Immature flat fish, generally plaice, fried but often ungutted, are ultimately found guilty in this most interesting argument. An area near the mouth of the Elbe was specially incriminated, and its disuse from 1912 tallies closely with the disappearance of the autumn typhoid rise, the danger of mines in this part of the North Sea being a deterring influence even since the end of the war, besides earlier voluntary agreements by fishermen to keep off these grounds. Sir William Hamer's whole argument is of compelling interest, and is indeed a romance of the prevention of disease.

#### *Veneral Diseases.*

The number of new cases dealt with at the hospitals in 1922 was 23,811, of which 6,809 were syphilis, 10,632 gonorrhoea, and 321 soft chancre. As compared with 1921 there is a decrease in every class—1,379 in syphilis, 77 in gonorrhoea, and 150 in soft chancres. Cases of syphilis are being earlier discovered since the clinics were established. The total attendances were 529,003, a notable growth, showing that the ratio of attendances to new cases continues to increase. Many cases come after exposure and are found not infected. Examinations of pathological specimens have largely increased, the number from treatment centres being 75,351, besides 18,507 from private practitioners. Failure to complete treatment is not so frequent as would appear, because the definition of cure is now much more strict than formerly.

#### *Medical Inspection of Schools.*

As school medical officer Sir William Hamer's report covers the usual ground. At the beginning of the year there was considerable prevalence of infectious disease, and "prevalence of throat maladies, scarlet fever, and diphtheria followed in 1921 at the usual interval of seven years upon the preceding waves, which had culminated in 1907 and 1914." Also there was "the usual periodical measles wave," its maximum mortality (115 deaths) being attained in the fourteenth week of the year. In addition, whooping-cough was unwontedly prevalent in the early months. Unemployment was abundant, and for retrenchment's sake compulsory day continuation schools were discontinued. In the first half of the year there was a falling off in attendance at treatment centres. However, three particularly satisfactory influences were at work: (1) Notable activity in "following up," especially as to tonsils, adenoids, and teeth; (2) increased progress in the personal hygiene of children; and (3) a comprehensive review by the Board of Education of school medical inspection and treatment in London.

Of 199,812 children examined at the three statutory age groups, 75,874 required treatment of some sort, and for one reason or another there were over 90,000 additional examinations. The number of children treated was under 200,000, or less by nearly 20,000 than in 1921. In dental treatment there was a decrease of nearly 10,000, and of nearly 7,000 for ear, nose, and throat defects, owing to the steady progress made in the previous years. Reinspections numbered 178,964, and the very satisfactory percentage of 77.7 was found to have been treated.

These are the principal statistics, and it is not proposed to enter here into further details of the year's work in London, but all who are engaged in school medical inspection and treatment will find much that is interesting and important in Sir William Hamer's report. What the Board of Education says may be noted in conclusion:

"Medical inspection and treatment have secured the sympathy and interest of parents. It is satisfactory to see the large groups of mothers at inspections, keen to know what they should do for their children and prepared to pay according to their means. It is an eloquent reply to critics who urge that the school medical service tends to diminish the responsibility of the parent in the home."

So long as that represents the position, so long as parents are keenly interested, and education authorities require that they pay according to their means, the scheme will be a success; and the sense of responsibility will not be diminished but increased by the education parents receive in the upbringing of their children, and in their own financial and family duty to the new generation of whom they are the natural guardians.

carried on haphazardly in an atmosphere of speculation, and with imaginative foresight he seized on this primary discovery. He was more fortunate still in securing as his colleague Dr. J. A. Murray, the present director, and the two of them literally flayed in the upper rooms of the old Examination Hall on the Embankment. It is impossible for an outsider to apportion to each his separate share in that successful partnership, but between them to quite a short time they made the laboratory the Mecca of cancer research. Workers interested in the subject came from all parts of the world to study. Balfour was a tireless enthusiast, endowed with a keen brain and highly critical faculty, a ready and resourceful speaker, and a writer with the gift of clear exposition. Placed as he was in such a position, secondly of the old methods, he had more than the necessary pugnacity to force the new work and the new ideas into merited prominence, and his name soon became world-famous. His contributions to the study of tumour growth are mentioned in the Scientific Reports of the Imperial Cancer Research Fund and in many scientific periodicals of this and other countries. They embraced much more than purely experimental or biochemical research: statistical investigations, the comparative pathology of tumours, the ethnographical and zoological distribution of the diseases, and numerous other departments of cancer research yielded their due portion to the harvest. In the nature of things clinical pursuits and utilitarian researches in surgical pathology were beyond the scope of the organization, but for those who have not closely followed the developments of our knowledge of cancer, and more especially those who are inclined to be impatient with the progress, and who are inclined to the need for the exploration of all possible (and impossible) avenues of revelation. It must not be imagined that the laboratory study of medical problems, attractive though it may be, is pursued in academic calm and cloistered ease, or that results are the outcome of God-given inspirations. There is the haunting fear that sustaining ideas and fertile resources may fail; and especially in a subject which so directly affects the lay mind there is no wonder that many retire from the struggle. Balfour's work on cancer extended over little more than ten years; there were signs before the war that the old brilliance and resource were fading, and he dropped away. We are reminded of Meredith's lines:

Re steadfast in that which impelled, for the peace  
Of Earth he who leaves must have trust;  
He is safe while he sows, but when faith shall cease  
Desponding he drops

But when all has been said in adverse criticism of him, his work still remains brilliant and intense, finished and accurate, suggestive and inspiring. He dominated cancer research, and he continued until the experimental production of cancer—a thing he longed for—became practicable, he would still have been the foremost figure in the adventure. To me, who knew him not very intimately during his heyday, he leaves behind none but pleasant memories, and I am grateful to have known him. He was, I think, a genius, and he did great work.

GEORGE E. KENNIE, M.D., F.R.C.P.,  
Consulting Physician, Royal Prince Alfred Hospital,  
Sydney, New South Wales.

We have already expressed our deep regret at the announcement of the death on August 10th of Dr. George Edward Kenne of Sydney. He was a distinguished student of the University College, London; he graduated M.B. at the University of London in 1887, and M.D., winning the gold medal, in 1888. Shortly afterwards he settled in Sydney, and was elected physician to the Royal Prince Alfred Hospital there. He devoted his attention specially to the neurology, and in that subject in particular was one of the most trusted consultants in New South Wales. Dr. Kenne was also visiting physician to the Mental Hospital, Sydney, New South Wales.

Sydney, and took a deep interest in the instruction of a formerly Commissioner of Lunacy for Scotland, who a little over a year ago was appointed professor of psychiatry in the University of Sydney. Dr. Kenne did not publish many papers, but all that he wrote was marked by wide knowledge, large experience, and an almost meticulous desire for accuracy. In order to refresh his knowledge he spent some time in this country about fifteen years ago, and took the opportunity of attending the practice of the National Hospital in Queen Square, and many members of its staff remember the courteous retiring man, whose wide acquaintance with neurology had to be discovered, as it was never paraded. Dr. Kenne discharged all the duties of physician to the Royal Prince Alfred Hospital with punctilious care, and when he retired last November under the age rule, on attaining the age of 60, he was appointed honorary consulting physician, and along with Dr. Dockley, who retired at the same time from the post of senior ophthalmic surgeon to the hospital, was entrusted to a complimentary dinner by the members of the honorary medical staff. He was deeply interested in the British Medical Association, and was President of the New South Wales Branch in 1903; for many years he acted as correspondent of this journal in New South Wales. He was also for a long period editor of the *Medical Gazette* variously known as Australian and Australasian; he only vacated office at the time of the amalgamation in 1914 which resulted in the establishment of the *Medical Journal of Australia*. His assiduity in earlier days paved the way for the success which has attended the *Medical Journal of Australia*. Dr. Kenne can have had no enemies. He had many friends, who respected him for his high character and rich attainments, and loved him for his gentle spirit and large charity.

THE REV. D. W. TORRANCE, O.B.E., M.B., C.M.,  
Medical Missionary of the United Free Church of Scotland  
at Aberdeen.

The death of Dr. David Watt Torrance at Tibberias on August 28th has removed one of the most striking personalities from the ranks of medical missions and a distinguished member of the medical profession. It is no mere metaphor to say that his life was a romance, and happily the story has been most effectively told in a volume published by Hodder and Stoughton entitled *A Galilee Doctor*. Here we see him as the brilliant student and then as house-surgeon at Glasgow Infirmary, the resourceful pioneer, the successful surgeon, the saintly combatting cholera epidemic, the friend of Jew, Turk, Moslem, or Christian, and above all the devoted disciple of Him who was known as the Great Physician on the shores of Galilee, where Dr. Torrance planted his hospital. Many members of the profession will be interested to read this thrilling story of one of their number who heard the call to service in one of the most difficult districts in the world. Two remarkable adventures indicate the spirit of this intrepid missionary. In the first instance he went out in one of his small boats, the *Clyde*, in the teeth of a furious storm on the lake to find his second boat, the *Katrin*, which had slipped from its moorings. The second incident tells of his motor car held up on a level crossing in front of an approaching train, and of his efforts to drag it from the line lest the train should be derailed. He was knocked down and rendered unconscious and suffered from shock. Torrance was born at Alford on November 6th, 1862, the son of a skilled surgeon and oculist, and the hereditary love for the medical profession has passed to his family, one son for the medical profession has passed to his family, one son of a skilled surgeon and oculist, and the hereditary love for the medical profession has passed to his family, one son of a skilled surgeon and oculist, and the hereditary love for the medical profession has passed to his family.

(4) that it is very simple and inexpensive, (5) that by its routine employment it will probably be possible to make treatment less empirical and more in accordance with the requirements of individual cases.

### STATISTICS AND PUBLIC HEALTH.

THE receipt of a copy of the second edition of Professor Whipple's manual on vital statistics<sup>1</sup> starts a train of reflections. Here is a volume of nearly 600 pages, almost wholly devoted to the illustration of statistical methods applied to the data of public health services. It has none of the general epidemiological features which would recommend such books as those of Prinzing or Sir Arthur Newsholme to the general medical reader; it displays no such mastery of modern mathematical theory as secures to Mr. Udny Yule or Professor Czuber a wide circle of readers. The outstanding merit of the book is its assumption that the medical reader will wish to acquire as practical a knowledge of this subject as he would expect to gain of any other essentially practical technique in the field of medical science. The student is told—no doubt not always quite accurately—what method he should apply to the study of a particular class of problem, and his progress is tested by real exercises. One finds such questions as these: "How would you find out what proportion of all children born have whooping-cough at some time in their lives?" "Do the statistics of infant mortality justify the continuance of the milk stations in New York City?" "Is there a higher correlation between flies and diarrhoeal diseases among children than between diarrhoeal diseases and other factors?"

One wonders, or rather one does not wonder, what sort of answers such questions would elicit from candidates for an English diploma in public health. But, in America, it has taken less than four years to exhaust an edition of such a book written, as the author says, "for students who are preparing themselves to be public health officials and for public health officials who are willing to be students." Nobody in this country could advise a student preparing himself to be a public health official to read such a book as Professor Whipple's; it would not help him to pass his D.P.H. examination. It is true that "vital statistics" are an item of the curriculum and that the General Medical Council has decreed that no less than twenty lectures shall be devoted to vital statistics and epidemiology. But since, so far as we are aware, the Council has not decreed that candidates shall be required to give practical proof that they have learned anything from the twenty lectures, the effect upon their actual statistical education will be precisely that of the reforms in the Inns of Court of sixty years ago, when the student might either pass an examination or attend lectures, but need not do both, the view being—as Bagehot said—that "to examine those who have already attended lectures would be impertinent; it would seem as if we doubted whether they had learnt from those lectures or not." In fact, in England, the serious academic study of medical and vital statistics is almost wholly confined to non-medical students. We believe that only at University College, London, is a distinct course of instruction in medical statistics offered, and that, in the last four years, it has been almost exclusively attended by non-medical undergraduate students for the B.Sc. and by non-medical post-graduates.

<sup>1</sup> *Vital Statistics: An Introduction to the Science of Demography.* By George Chandler Whipple. Second edition. New York and London: Chapman and Hall. 1923. (Pp. 579. 20s. net.)

In America the state of affairs is different. At two of the great universities—Johns Hopkins and Harvard—maintain whole-time professors of statistics, and from the department of the Johns Hopkins Professor, Dr. Raymond Pearl, have issued a long series of medico-statistical studies. If it were not for the Ministry of Health and the Medical Research Council, there would be no whole-time medical statisticians in this country—all medical statistical research would necessarily be the leisure employment of men engaged in other fields; neither the Ministry nor the Council can be confident that it will be possible to maintain a succession of trained men. Yet this lack of encouragement is a serious matter, because in most branches of medicine, and in that of preventive medicine above all, the power rightly to use the statistical method, whether as an instrument of research or of critical evaluation, is a most valuable accomplishment. Indeed, the unquestionable fact that the power of the statistical method may be overestimated is an additional argument for a wider dissemination of knowledge of its strength and weakness. It is always dangerous for important knowledge to be the exclusive property of a small minority. In the days of collective and international investigations and comparisons, many of the data upon which action is based must partake of the statistical character and be adjudicated upon by methods of statistical logic.

There is a very wide difference between the standards both of material accuracy and scientific analysis reached in the presentation of data of mortality and morbidity in different countries. In many perhaps in all, the less advanced nations, there is a need of and desire for instruction. America can offer that instruction in her universities. What do we here? The intelligent foreigner, recognizing that it is to great Englishmen—to such as Farr and Professor Karl Pearson—that modern practical statistics owe their greatest improvements, but noting that we ourselves seem to attach little material importance to statistical knowledge, might be pardoned if he concluded that England was not the country in which to study medical statistics. Whether the new School of Hygiene can help to remove this reproach we do not know, but it is certain that a new professor or a new army of professors, cannot change the internal situation unless it is made manifest that it pays a student to acquire a sound knowledge of medical statistics. Satisfactory teaching facilities might meet the needs of foreign or overseas post-graduates, but few of our own students will study a subject knowledge of which neither carries marks in an examination nor credit in candidatures for public appointments.

### THE NEW MINISTER OF HEALTH.

It is unfortunate that Mr. Neville Chamberlain's recent success as Minister of Health should have led to his transfer to an office generally and by tradition held to be one of the highest in the Government. It is unfortunate also that the office of Minister of Health should so frequently change hands, and Mr. Chamberlain has himself expressed his regret that he should have to leave work in which he was strongly interested before he could complete the schemes he had instituted or developed. Sir William Joynson-Hicks, who has now become Minister of Health, brings to his office a reputation greatly strengthened and enlarged during the last few months. During some ten years as a private member of Parliament he interested himself particularly in air service and road transport, and

Systematic practical training in the inspection of meat at a carcass market. A course for health visitors and child welfare workers begins on October 1st: the course of lectures is arranged as a preparation of the health visitors' examination for the Royal Sanitary Institute, and is not part of the scheme of the Board of Education. All students who wish to attend, but only those who hold the necessary and satisfactory qualifications set out in the regulations can be admitted to the examination. An introductory lecture to the students of the various courses will be given at the Institute by Professor H. R. Kenwood, C.M.Sc., on September 24th, at 5.30 p.m.; admission is free. Particulars may be obtained from the secretary of the Royal Sanitary Institute, 90, Buckingham Palace Road, London, S.W.1.

The Medical Branch of the Board of Education has been transferred from Nos. 5 and 6, Clements' Inn, Strand, W.C.2, to 54, Victoria Street, S.W.1. (Telegraphic address: "Medication Society, London.")

The annual general meeting of the Medical Scheme, annually, and Life Assurance Society will be held at the offices of the company, Lincoln House, 300, High Holborn, W.C.1, on Monday, October 1st, at 4 p.m.

A course of elementary lectures on infant care, for infant welfare workers and others, will be given by Dr. J. S. Hall, Fairbairn and Lady Barnett, M.D., in the Lecture Hall of the National Association for the Prevention of Infant Mortality and for the Welfare of Infancy, Carnegie House, 117, Widdowbery, W.1, on Mondays, at 6 p.m., from October 1st to December 3rd.

The Scottish Board of Health (121a, Princes Street, Edinburgh) announces the opening of its *Register of Health Visitors*. Persons discharging on behalf of a local authority all or any of the duties of a health visitor under a scheme of maternity service and child welfare or of tubercularists or otherwise, or of a school nurse under a scheme of school health administration, may apply for certification and registration.

A NATIONAL exhibition demonstrating the various

ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal*. Contributors who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

As, owing to printing difficulties, the Journal must be sent to press earlier than hitherto, it is essential that communications intended for the current issue should be received by the first post on Friday, and lengthy documents on Monday.

Authors desiring reprints of their articles published in the *British Medical Journal* are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

In order to avoid delay, it is particularly requested that all letters on the editorial business of the Journal be addressed to the Editor at the Office of the Journal.

The postal address of the *British Medical Association* and *British Medical Journal* is 429, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR of the *British Medical Journal*, *filology*,  
London; telephone, 2530, Gerrard.  
2. MANAGING, SECRETARY AND BUSINESS MANAGER  
(Advertisements, etc.), *friculate*, Westland; telephone,  
2630, Gerrard.  
3. MEDICAL SECRETARY, *Medicorum*, Westland; London;  
telephone, 2530, Gerrard. The address of the Irish Office of the  
*British Medical Association* is 16, South Frederick Street,  
Dublin (telegram, *Brilliant*).  
and of the Scottish Office, 6, Rutland Square, Edinburgh  
(telegrams: *Associate, Edinburgh*; telephone, 4761, Central).

gas in the home and industry, will be held at the Bingley  
Hall, Birmingham, from September 17th to October 3rd.  
At the International Congress against Alcoholism held at  
Copenhagen from August 19th to 24th it was decided to  
appoint a small committee to draw up a scheme for an Inter-  
national Federation of Medical Abstinists. The members of  
the committee were Dr. Hollnesser (Czechoslovakia), the  
convenor of the meeting, Dr. C. E. Harford (England), Dr. M.  
Legrain (France), Dr. K. Heycheit (Belgium), and Professor  
R. Vogt (Norway). A constitution was agreed upon which is  
to be submitted to the existing societies of medical abstinists  
in different lands. The object of the Federation is to unite  
these societies: (1) to promote total abstinence in the medical  
profession; (2) to study alcohol and alcoholism; and (3) to  
organize the scientific attack on alcoholism. It is proposed  
that the Federation shall hold its chief meetings on the  
occasion of the International Congress against Alcoholism,  
but would meet also at international medical congresses.

A practical post-graduate course in gynaecology will be  
held at the Hôpital Broca, Paris, from September 17th to  
29th. The fee is 150 francs.

An amendment has been made to the law controlling  
medical practice in Ontario, which has closed the door against  
osteopaths, chiropractors, and other "drugless healers,"  
unless they hold the qualifications which the Medical Council  
requires of medical practitioners.

A vacation course will be held at the Hôtel-Dieu, Paris,  
from September 10th to 21st, on recent medico-surgical  
work on alimentary diseases.

Professor LITTORÉ, the well known ophthalmologist,  
who recently resigned the chair of ophthalmology at Breslau,  
died on July 31st.

DR. SEBASTIAN RECESSES, the well known gynaecologist,  
and dean of the Madrid Faculty of Medicine, has left Spain  
to visit the universities of South America, where he will  
lecture on gynaecology.

young girl who is passing three or four pounds of liquid stool in twenty-four hours. Abdomen somewhat tympanitic; not much elevation of temperature or severe pain. No signs of glandular swelling in abdomen or elsewhere. This morning.

The late Dr. Flora Murray, who died on July 28th, left estate of the gross value of £3,941, with net personality £3,335. She left all her property to Dr. Louisa Garrett Anderson, desiring her to dispose thereof as she may think best, retaining for her personal use all or any part of it as she might wish.

Dr. Alexander Marmorek, the well known bacteriologist, died recently in Paris at the age of 86.

The German Pediatric Society will hold its annual meeting at Göttingen on September 21st and 22nd, when a discussion will be held on endocrine glands, in which Drs. Schmidt of Berlin, Birk of Tübingen, Thomas of Cologne, and Goetz of Munich will take part.

turn has led to a thorough recasting of the book in its second edition.<sup>1</sup> It aims to provide a clear statement of the considerations that arise when a binding estimate has to be made of the incapacity arising from any and every accident or occupational disease, and to show in each case the percentages of disability which so far have been accepted as sound either by the law courts or by other authorities. The standpoint is, of course, French, and neither ideas nor the law on the subject in France are quite on all fours with their equivalents in Great Britain; nevertheless both lawyers and medical men in this country may derive from it some useful hints when specific cases are in question. In the early years following the passage of the French law there seems to have been considerable difficulty in reconciling legal and medical views concerning the results of accidents, owing in part to the medical view that no assured prognosis of the economic results of an accident was possible, and in part to a difference of opinion as to what the term "accident" meant. The legal view was that an accident meant any lesion arising from the violent and sudden action of any cause external to the body. The medical view, on the other hand, was that an accident was any sudden and unforeseen occurrence which produced a lesion or temporary or permanent functional trouble. It was the former view that eventually prevailed and its acceptance was finally imposed on the medical profession by a decision of the court of appeal in 1912. Since then legal views on the subject of compensation cases appear to have almost eliminated any consideration of accident in the common sense of that term, with the result that any lesion or disorder which can be attributed to work, however normally performed, is now regarded in France as an "accident" and as *ipso facto* entitling the individual to compensation. A further point of some interest is that French law clears the decks of all questions of contributory negligence or responsibility for an "accident." The French employer is in every case liable to pay up to half the employee's normal wage, not only to the employee himself during his life, but also in the case of his death to any persons who may have been dependent on him. The workman is urged to avoid accidents if he can by the fact that whatever may have been the cause of the accident he can in no case and whatever the degree of his resulting disability obtain more than half his previous wages. The authors refer to disability scales in use in some foreign countries and point with approval to the principle underlying one adopted by the Germans in 1920. This is that every injury shall be assigned at least two percentages in any scale of resulting disability. Hence when an injured person, although to some extent disabled, is still capable of pursuing his original occupation only the minimum allowance for his particular degree of disability is assignable. The maximum for that degree is reserved for cases in which the disability, although no greater in itself, necessitates the adoption of some other means of livelihood than that pursued by the individual previous to his injury.

#### SPIRITUAL HEALING.

IN the *Times* of August 27th there was a report of an address given in Westminster Abbey by the Rev. R. C. Griffith, vicar of St. Benedict and of St. Martin-at-Palace, Norwich, on "Spiritual healing." The address was noticed also in some other papers. The vicar stated that the spiritual healing work of the Church is a really live thing in this country. "I myself," he said, "have seen blind people see. We have seen one with a withered arm for sixteen years hanging at her side suddenly shoot it out

perfectly whole. We have seen cancers disappear in twenty minutes. . . . The enemy who deliberately attacks this work say that to try and encourage people to expect to be healed and then find that they are not healed is a wicked thing because the people lose their faith. That is a blasphemous lie." Mr. Griffith added that he had seen thousands of people waiting outside two little slum churches from 9 a.m. to 11.15 p.m., kneeling in the gutters and praying for those on whom hands were being laid in the two little shrines. It is not surprising, perhaps, that an address of this kind should occasionally be given by Anglican clergymen, but it is surprising that it should be given in Westminster Abbey. Before the war a Committee of Inquiry into Spiritual, Faith, and Mental Healing, consisting of clerical and medical members, used to meet at Westminster under the chairmanship of the Dean. In its report, published in 1914, the Committee stated that "they are forced to the conclusion, after the most careful inquiry, that 'Faith' or 'Spiritual' healing, like all treatment by suggestion, can be expected to be permanently effective only in cases of what are generally termed 'functional' disorders. The alleged exceptions are so disputable that they cannot be taken into account." The first signature to this report is that of Bishop Ryle, Dean of Westminster. The publicity given to such addresses is harmful for the reason which the vicar puts into the mouth of the "enemy." The person who is led to expect to be healed and then finds he is not healed, even though his religious faith be too strong to be disturbed, will be apt to lose hope. As Mr. McAdam Eccles has said in a letter to our contemporary, there should be co-operation between clergy and ministers and members of the medical profession, but the diagnosis at least should be in the hands of the doctor. We would suggest strongly to Mr. Griffith that he would be wise in making very sure of his evidence before he makes dogmatic statements with regard to cure; especially if the statements are such as may lead other sufferers to neglect early treatment by operation or otherwise. We do not for a moment deny the benefit derived in suffering from faith. Nor do we dispute the occasional happening of unexpected cure in apparently hopeless cases. The Westminster Committee proposed, after issuing its preliminary report, to direct its attention to a careful inquiry "into the evidence for cases of asserted cure by 'Spiritual' or 'mental' healing of organic or other serious disorders submitted for investigation." Unfortunately the activities of the Committee were cut short by the war; but Mr. Griffith and those among the clergy who are disposed to accept his teaching will find food for reflection in the evidence of certain faith healers who appeared before the Committee.

#### THE INVESTIGATION INTO DISTEMPER.

AS has been previously noted in this JOURNAL, an organized attempt is being made by the Field Distemper Council, with the co-operation of the Medical Research Council, to discover the cause of distemper in dogs in order to arrive at the control or cure of the disease. Distemper is a disease which has puzzled pathologists for many years, and many different theories have been advanced from time to time to explain its ravages. Many observers have described a bacillus, commonly found in distempered dogs, and have looked upon it as the cause of the disease. Others, again, have regarded the bacilli so found as secondary invaders and not the causal agent of distemper; the primary infection they consider to be due to some hitherto unrecognized agent. The experimental work of Carré appears to show that the disease is due to an ultra microscopic filtrable virus. The confusion existing at present makes it desirable that the research now proposed

electrolytes, tending to come out of solution on dilution; its precipitating action is therefore augmented on dilution; pseudoglobulin, on the other hand, is soluble in water, and therefore its capacity to hold gold in solution is diminished by dilution. The increased precipitating action of euglobulin in dilution appears to be responsible for the precipitation curve which has been described as typical of tabes. Probably all cerebro-spinal fluids contain a constant quantity of pseudoglobulin, but variable quantities of euglobulin. The tabetic curve is due to a small increase in euglobulin, which manifests its action only in the intermediate dilutions, when its tendency to come out of solution is augmented to a maximal extent by dilution. In general paresis, on the other hand, the euglobulin is increased to such an extent that it overcomes the inhibitory action of the pseudoglobulin, and precipitates colloidal gold in the first dilution of the gold sol test. It is possible also that pseudoglobulin as well as euglobulin may be increased in certain luetic conditions. This hypothesis would explain why precipitation of neutral colloidal gold is always produced by paretic cerebro-spinal fluid, sometimes by tabetic fluid, but never by normal fluid; and also why cerebro-spinal fluid obtained from definite cases of general paresis often gives the precipitation curve assumed to be characteristic of tabes. Other experiments carried out by these authors have shown that the precipitating substance is non-dialysable, is precipitated by half saturation with ammonium sulphate and by 50 per cent. alcohol at 0° C., and is destroyed by heat at temperatures depending upon the reaction of the fluid and the duration of heating.

#### FUNGI OF FROZEN MEAT.

The department of Scientific and Industrial Research of the Food Investigation Board has just issued a report, by F. T. Brooks and C. G. Hansford, on mould growths upon cold-store meat.<sup>1</sup> The more detailed and technical part of their report has already appeared in the transactions of the British Mycological Society; but the six pages give a clear and useful account, in plain language, of the kind of mould that grows under conditions of cold storage. Putrefactive bacteria, whose growth is inhibited by low temperatures, cause meat to go bad, but the moulds that grow at temperatures about or below freezing point are harmless, although they give the meat a disagreeable appearance. The best known, the most unsightly, and the most serious from the economic standpoint is the *Cladosporium herbarum*, which causes what is known on cold storage meat as "black spot." It will grow at a temperature of 18° F. Other characteristic moulds are the white and the bluish-green moulds. The former are of two varieties—one, the *Sporotrichum carnis*, which has not hitherto been described scientifically, causing small white spots, and the other the moulds which give rise to the profuse growths known in the meat trade as "whiskers." These growths project for more than an inch beyond the surface of the meat, but collapse when exposed to a relatively dry atmosphere. The bluish-green moulds belong to the well known genus *Penicillium*, commonly found in cheese and on rotten apples and oranges. Another form of growth, that almost invariably arises on meat exposed to a temperature a degree or two above freezing point, consists of small colonies of certain yeasts, either pink or white in colour. When dry the white colonies frequently assume a brown colour, the "brown spot" referred to by other workers on meat moulds. These colonies of white yeast are difficult to distinguish from groups of bacteria, although in view of their relative significance in condemning meat or otherwise it is important

to do so. The practical lessons which are learnt from report are the necessity of cleanliness in abattoirs, cooling the meat as rapidly as possible after slaughter, so as to avoid mould spores settling on it before it is in cold storage, and the maintenance of a temperature in cold storage chambers of 10° to 15° F. Where chambers get badly contaminated with mould spores, meat should be removed and the chamber thoroughly cleansed with disinfectants before fresh meat is placed in it. But it is comforting to know that the mould growth is innocuous, and can be removed easily from the surface of the meat, or can be cut away when they grow in the skin, as in the case of "black spot."

#### INTERNATIONAL CONFERENCE OF RED CROSS SOCIETIES.

THE eleventh International Conference of Red Cross Societies, organized by the International Red Cross Committee of Geneva, began at Geneva on the afternoon of August 28th, and ended on September 1st. The conference opened with a meeting of special delegates, one from each National Society, and of members of the International Committee, to form a bureau and draw up a programme of business. This was followed by the opening general meeting presided over by the venerable international jurist, M. A. Dore, once President of the Swiss Confederation, and for many years President of the International Red Cross Committee. In the course of his address M. Dore referred to the work of the Red Cross and touched on the efforts that had been made during the past year, but without success, to come to an agreement with the League of Red Cross Societies. An animated discussion followed the reading, by Dr. Depierre of the Belgian Red Cross Society, of a letter from the other delegates of the United States, intimating their reasons for not attending the conference. A committee of fifteen was appointed to study the question of amalgamation and report on it by June, 1924, and there the matter rests for the time being; the views of delegates regarding this committee were expressed at a private meeting held on the morning of August 30th. In other respects, the business transactions during the conference was uncontroversial. Committees were set up to study and report on such questions as general Red Cross finance and the formation of a special reserve of funds, and the drawing up of a code for dealing with civil populations in occupied enemy territory or civilians interned in enemy belligerent territory. Senator Cirialao, President of the Italian Red Cross, gave an address on the personnel and stores needed for use during sudden calamities. The various committees met in the afternoons; at the morning sessions a delegate from each Red Cross society gave a summary of the work carried out by his society since the last international conference in April, 1921. This year's conference at Geneva was attended by delegates from forty-four national Red Cross societies and from thirty-eight Governments, and twenty-two representatives of charitable and humane societies attended by invitation. Two receptions were held, one on the evening of the opening day and another on the evening of August 31st.

A course of lectures on problems of personal and public health will be delivered in the lecture hall of the Royal Institute of Public Health, 37, Russell Square, London, W.C.1. The first lecture will be delivered on October 17th, at 4 p.m., by Dr. Alfred Greenwood, M.O.H. for Kent, and subsequent lectures will be given on succeeding Wednesdays at the same hour. The lecturers will include Professor J. C. Drummond, of University College, London, Major H. Graeme Anderson, Dr. W. A. Bullough, Dr. Kate Platt, and others. The Harben lectures will be given by Professor C. Levaditi, of the Pasteur Institute, Paris, on December 11th, 12th, and 13th, on (a) neurotropic virus (encephalitis); (b) neuro-vaccine; and (c) new discoveries in the treatment and prophylaxis of syphilis.

**Drugs.**—For drugs and appliances about £1,212,000 was paid to chemists and about £180,000 to doctors. Prescriptions were unusually numerous in the first quarter of the year, and the total dispensed by chemists was about 33,400,000, or 3,200,000 more than in 1921-22. Arrangements for standard dressings of superior quality came into force on March 1st. In respect of inquiries into extravagant prescribing, arrangements are being made which it is hoped will lead to more uniform administration.

**Standard of Treatment.**—Supplementary grant voted to provide a satisfactory standard of service was withheld from 121 doctors and 16 chemists, the total withheld being £2,175. In one case £300 was withheld from a practitioner for failure to notify the Insurance Committee that he had ceased to employ a permanent assistant, and £200 was withheld later from the same practitioner for not employing a whole-time permanent assistant. Sums of £100 and £80 were withheld for failure to provide proper treatment, £75 and £50 for not keeping records, and £50 for irregular certification. These were the largest amounts withheld. Among chemists, sums of £1 to £5 were withheld for various offences, such as refusal to dispense, alteration of a prescription, and inaccurate dispensing. During the year the Minister of Health received six representations for removal of doctors from the panel and five for removal of chemists. In two of the six medical cases the name was removed, one of them on a conviction for manslaughter. Two of those not removed had £100 supplementary grant withheld. There were only twenty-nine appeals against decisions of Insurance Committees regarding medical benefit. Of eighteen cases where doctors or chemists were the appellants, nine were dismissed, four allowed, three withdrawn, one decision was varied, and one appeal had been made outside the prescribed time.

**Schemes of Additional Benefits.**—The schemes adopted by approved societies with valuation surpluses have mostly been in operation for a year and nine months. Extra cash benefits have been easily administered, but other benefits have passed through a tentative and experimental stage, and in about fifty cases variations have been sanctioned. Until recently, indeed, many societies have found difficulty in spending the whole of the sums available. It is a common practice for societies with limited resources to require the member to pay a part of the charge made by the dentist, optician, etc., but during a period of excessive unemployment some members could not meet their obligation in that respect, and the Department has allowed societies to disburse for the time the whole amount, recovering the member's share by instalments. It appears from the report that the favourite non-cash benefits have been dental treatment and optical treatment, hospital or convalescent home treatment, and the provision of medical and surgical appliances. Amongst these, the provision of dentures stands easily first, and it is remarked in the report that looking to long years of neglect it is not to be wondered at. Societies are not entitled to set up clinics for the purpose, the benefit taking the form of payment for treatment. Also, there are no panels of dentists. The societies can, within their means, pay directly to members on their production of receipted bills, or pay in accordance with arrangements with any selected registered dentists, or through institutions or agencies. The Department cannot interfere in disputes arising out of arrangements to which it was not a party. Similarly, it is pointed out, the best way to utilize the £280,000 a year available for hospitals and convalescent homes is to be determined by the committee of management of each society. The larger societies have arranged with the British Hospitals Association on a basis of the duration of indoor treatment of members, and some smaller societies have arranged with local hospitals, also in respect of in-patients only, all the others being outside the scheme. Some societies, having members whose occupation involves eyestrain, have found optical benefit of particular use, and not very costly. The popularity of non-cash benefits has led to proposals for their extension; massage, radiant heat, electrical treatment, brine baths, and laboratory facilities have all been suggested. In concluding this part of the report, the Ministry holds it clear that such additional benefits have been most useful, and will react favourably on the

prevention of sickness, and eventually reduce the claims on the benefit funds. Insured persons and societies are reaching like conclusions as to the advantage of extending treatment benefits rather than cash benefits, and it is confidently believed that when the second valuation of societies is made the schemes adopted for utilizing surpluses will show a substantial advance in the provision of such facilities. That valuation, it may be noted, is to be made for some societies as at the end of 1922, and for others as at the end of 1923, the object being to spread over a longer period the heavy departmental work involved.

**Regional Medical Officers.**—This is the last matter of which we propose to make mention. When these officers were appointed in 1920 they were intended to deal not only with questions of capacity or incapacity, but also to consult with the practitioner in cases of admitted incapacity, as to restoration to health. Only the former function was undertaken at first, and only in urban areas containing about three-fourths of the total population of the country. The service was extended in the autumn of 1922 in respect of both these limitations. The references to the regional medical officers in England in 1922 totalled 103,010, of which 36,749 related to men and 66,261 to women; 101,033 were referred by societies, 1,426 by practitioners, and 41 by Insurance Committees. However, 23,022, or 22.3 per cent., failed to present themselves for examination; 19,361, or 18.7 per cent., declared off the funds without attending for examination; 18,918, or 18.4 per cent., were found capable of work, and 41,745, or 40.5 per cent., incapable of work. In Wales, for which the statistics are given in Part 5 of the report, the corresponding percentages were: failed to appear, 23 per cent.; declared off the funds without examination, 20 per cent.; capable of work, 22 per cent.; incapable of work, 35 per cent.

## Nova et Vetera.

### A MEDICAL LIBRARY TWO HUNDRED YEARS AGO.

In a previous contribution\* to *Nova et Vetera* some account was given of a remarkable sale of books belonging to Sir Robert Sibbald, the noted founder of the College of Physicians and the Botanic Garden of Edinburgh. The sale by auction took place in 1723; it must have aroused considerable interest in the medical profession and amongst scientists at the time; and it may even have led London buyers to face the dangers of the Great North Road to attend it. It will not be uninteresting to glance at some of the books which tempted bidders on that winter's day (February 5th, 1723) in Edinburgh two hundred years ago.

The distinctively medical works in Sir Robert Sibbald's library numbered 799; there were 136 folios, 274 quartos, and 389 of octavo size or smaller. Seventeenth-century works predominated; but there were also many of the sixteenth century and one or two of the fifteenth.

The highest price (£10 18s.) was obtained for the Paris edition of the works of Hippocrates and Galen; it was entered as "*Hippocratis et Galeni Opera Gr.Lat. cum Notis Charterii, in 10 vol. Lutetia, 1679*"; and it may be that it was bought for the Royal College of Physicians, which has this edition; it bears no trace of Sibbald's name, but this may be due to the fact that it has been rebound. Another edition of Hippocrates was that of Geneva (1657); it was entered as "*Hippocratis Opera Gr.Lat. cum Notis Foesilii*." From the marginal prices in ink and pencil in the copy of the catalogue which the present writer has before him it would appear that the original owner of the catalogue had been ready to bid a guinea for the work, but it was sold for £1 7s. Another book which brought a good price was a Stephanus edition of *Medicæ Artis Principes post Hippocratem et Galen.* of 1567; it was bought for £2 10s. Most of the medical works, however, even among the folios, brought only one or two shillings, the quartos and more especially the octavos went for less, sevenpence being a not uncommon figure.

The languages in which most of the medical works of two hundred years ago were written were clearly revealed by the catalogue: among the 136 folios only four were in English and one in French; the remaining books were nearly all in

British Medical Association.

MEETING, 1923.

Sir Thomas J. Holden, Bt., M.D., F.R.C.P., President.

DISCUSSION ON DIABETES AND INSULIN.

PRESIDENT'S INTRODUCTORY REMARKS.

What the Committee of this Section met to arrange the discussions which form its chief business, one subject occurred to all of us as being apposite. The fact which I had just chosen to discuss for our next discussion was, of course, the introduction of insulin as a remedy for the disease. If we do not discuss insulin at this meeting of the Association our patients will be much surprised, and with good reason. If we do not discuss it they will probably be agitated, and for good reason, that we are, for "cure," and that nothing more needs to be said on the matter. I am afraid a good many persons have already assumed this, and perhaps such an assumption is not surprising in view of certain generalizations that have got abroad and which, if they do not carry the hall-mark of authority, at least have not been authoritatively contradi-

It is notoriously difficult to control popular ideas about new remedies. The wish is so much rather to the thought of the very fact that such epoch-marking events as the discovery of insulin are rare takes popular credence, when they do come, rather than when the disease is a common one, as diabetes is; when it often brings our best efforts, and terminates in dramatically fatal fashion, as diabetes does; then the public is on the tip-toe of expectation as to what promises speedy results. The problem is regarded as being already solved, whereas it may well be that the successful preparation of this internal secretor of the pancreas will prove to be as great an asset to medical science by assisting the interpretation of phenomena hitherto obscure, as in the provision of a therapeutic agent in diabetes.

Only a superficial reader will read into these remarks a deduction from the great value of Dr. Banting's discovery; in reality such remarks enhance its value. Has not the essence of the problem of diabetes hitherto been the almost certain fact that under that name we have been dealing not with one biochemical disturbance only, but with several? It seems probable that the use of insulin, controlled by careful observations, will not only still further establish this fact but will also help to mark off much more clearly than before, certain very different types of cases of diabetes met with in practice. One result of this segregation we are already observing: certain cases of diabetes are benefited much less by insulin than are others, and this is so even when we make due allowance for all those collateral points in the dietetic part of the treatment, attention to which we know to be so important. Certain cases will, doubtless, be found not to be benefited at all. And if we do not make this position quite clear we shall see many patients suffer the bitter fumes of disappointment after entertaining a false hope for which we may, quite unwittingly, have been partly responsible. Some very fundamental questions will be discussed to-day, and we shall hear the opinions of men who are well qualified to speak upon them. (1) If, as someone has aptly put it, insulin acts as a walking-stick to a lame pancreas, will some of the cases of diabetes that show such striking improvement under treatment by this remedy recover their lost power of maintaining a normal "blood sugar," so as to carry on without its help? (2) This question

## Scotland.

### CHANGES IN EDINBURGH UNIVERSITY CURRICULUM.

CONSIDERABLE changes in the course of study for medical students have been introduced as a result of relegating inorganic chemistry and physics to a preliminary examination which must be passed before the student registers for medical studies. The period thus gained is to be devoted towards utilizing the latter part of the curriculum for a more intensive study of medical subjects proper, as distinguished from the subjects of general medical science such as physiology, anatomy, pharmacology, and pathology. A considerable gain both in arrangement of study and in the length of time devoted is obtained for the clinical subjects, to which the student will in future devote three hours daily in the third year, the greater part of each day in the fourth year, and the whole day in the fifth year. According to the old arrangement, by which medicine and clinical medicine were taken in the third year along with pathology and pharmacology, the student, being confronted with the immediate prospect of examination in the two latter subjects, paid little attention to medicine and found himself at a corresponding disadvantage when the time of the final examination in due course arrived. By the new arrangement, which comes into force in October, 1923, the year of study is divided into three terms, autumn, spring, and summer, which are of equal importance. At the end of his second year, and before he approaches the clinical subjects, it is intended that the student should have a short course in "human" as distinct from "scientific" physiology, and in applied anatomy. In the third year the student will approach the study of medicine with an elementary course of fifty lectures in the autumn term, and will have a similar introductory surgical course of fifty lectures in the spring term, and a similar course of lectures on clinical therapeutics in the summer term. For clinical work in the third year, the whole number of students of the year will be divided into two sections, so that in small groups they will have introductory courses in clinical medicine, in minor surgery, and in clinical pathology, microscopy, and chemistry. Each of these three introductory clinical courses will occupy the hours from 11 to 1 throughout one term. The afternoons throughout the third year of study will be occupied by materia medica and pathology, in which the student is examined at the termination of this year. In the fourth year the students of the year will be divided into three groups to be known as the medicine group, specialties group, and surgery group respectively. All of these groups will attend together fifty lectures on midwifery in the autumn term, fifty lectures on advanced medicine in the spring term, and fifty lectures on advanced surgery, as also lectures on public health and on forensic medicine, in the summer term. As regards the clinical work of the fourth year, in the autumn term the medicine group will spend the hours from 11 to 1 in medical ward work and will attend clinical courses in fevers and vaccination in the afternoons. The surgery group will occupy itself from 11 to 1 with surgical ward work and anaesthetics, and with out-patient visiting in the afternoons. The specialties group will devote the hours from 11 to 1 to special clinics, such as those in the ear, nose, and throat, skin, and ophthalmological departments. In the spring term of this fourth year the students previously constituting the medicine group will become the surgery group, and those who in the autumn term formed the surgery group will change over to the specialties group. A similar change will be made at the beginning of the summer term. In this way every individual student of the fourth year will have had three periods of three months concentrated successively upon the study of clinical medicine, clinical surgery, and clinical specialties. During the fifth year there will be no systematic lectures to attend. There will be again a division into three groups, which will in rotation for three months each take up clinical medicine, clinical surgery, and clinical midwifery with pediatrics. The clinical medi-

cine group will, in addition to clinical ward work, attend tuberculosis clinics and visiting of out-patients; the clinical surgery group will include in its work venereal diseases and operative surgery; and the clinical midwifery group, in addition to attending deliveries, will study ante-natal clinical work and diseases of children. With this intensive clinical work, which frees the final year from systematic lectures and aims at preventing that dissipation of thought and energy which is incidental to studying widely different subjects in the successive hours of each day, the student ought to be better fitted to meet his final examination and much better fitted for the subsequent responsibilities of practice.

## England and Wales.

### VOLUNTARY HOSPITALS COMMITTEE FOR LEICESTERSHIRE AND RUTLAND.

WE have received from the Voluntary Hospitals Commission, Ministry of Health, the first report, dated July, 1923, of the Voluntary Hospitals Committee for Leicestershire and Rutland.<sup>1</sup> The Commission's opinion that the group territorially of the two counties would produce an efficient working unit seems to be borne out both by the report and by a map embodied in the report showing the places from which patients were received into the Leicester Royal Infirmary during the year 1922. Mr. T. Fielding Johns was appointed chairman of the Committee. The Leicester City Council was represented by Mr. C. J. Bond, F.R.C.S.; the consulting staffs of hospitals by Mr. W. I. Cumberland, F.R.C.S.; the medical profession of the city and county of Leicester by Drs. W. Moffat Holmes and R. R. W. Logan; and the Rutland medical practitioners by Dr. F. H. Wallage. Dr. R. H. Fagge was one of the representatives of the Voluntary Hospitals Commission.

The Committee dealt first with its duty of advising the Commission on applications from voluntary hospitals within its area for a share in the Government grant of £500,000. Of eleven hospitals approached on the matter, only two made application for a grant. In the case of the Leicester Royal Infirmary, the Commission approved the recommendation of the Committee, and made a grant upon conditions which were accepted by the Infirmary authorities. In the second case no grant was made. The Leicestershire and Rutland Committee then turned its attention to the next two terms of its reference: first, to collect information as to the needs of the area; secondly, to further co-operation between hospitals. Six tables are given in the report showing the accommodation and possibilities of service in the area, in addition to the map to which we have referred. From this map the Committee notes the well known tendency of patients to seek treatment from a central institution, passing by local sources of help in their journeys thither. The unique position of Leicester as a hospital centre and the facilities for co-ordination of service and for transport by ambulance are also shown. The Committee states that although the services in the counties are numerous and extensive no serious attempt has been made towards co-operative medical service or unification. Especially is this the case with regard to the auxiliary hospitals which might play an important part in an efficient hospital service for the area. These hospitals have no definite standard to which they can be called upon to conform. In some cases a local hospital fails to attract all the patients it might attend because only a portion of the medical practitioners of the area are attached to it. There is a disinclination to place patients under the care of a rival practitioner in the local hospital, and the waiting list of the central institution becomes congested. A consistent of the central institution becomes congested. A contributory factor may perhaps be the feeling that such an institution must be better equipped both in personnel and material for dealing with serious cases—to the patient his own case is always serious.

To assist the Committee in considering hospital co-operation and co-ordination Messrs. Bond, Cumberland, and

<sup>1</sup> Leicester Co-operative Printing Society, Ltd., 99, Church Gate.

## Correspondence.

### MEDICAL CHARITIES.

SIR,—Under the above heading, during the past few weeks, I have watched wistfully the expressions of individual and collective beneficence; at long last, as one officially interested in the welfare of the Medical Foundation of Epsom College, I venture to plead on its behalf for a share of the publicity that, for better or for worse, has been monopolized by the very excellent Royal Medical Benevolent Fund. Like it, Epsom College dispenses many pensions—168 this year, if I remember rightly—to aged or disabled medical men, or if deceased to their dependants. But our greater work, and that that makes the more intimate appeal to the sympathies of our profession, is the bestowal of fifty foundation scholarships on the needy sons of deceased or disabled medical men. These afford, free of any charge whatsoever, a complete school education at Epsom College, which otherwise is a public school of the ordinary type, open to all, like Eton, Winchester, and the rest. The competition for these is keen and widespread. Writing away from London, I think I am correct in saying that the first boy on this year's list of six was the son of a widowed medical woman practising in India; and two other boys were the sons of fathers who held Scottish qualifications; this seems to guarantee the catholicity of our benefactions. For the maintenance of these scholarships, and for all that they imply and involve, we depend in the main on the generous support we receive from the annual subscriptions of members of the medical profession. With increased pecuniary support we could do much more, and do it better also.

Information as to the purpose and needs of the Medical Foundation will be gladly supplied by our Secretary, at 49, Bedford Square, London, W.C.1, or by myself, and the Secretary would also receive most gratefully any such help as has been foreshadowed in the letters that have appeared in your recent issues. My mind's eye looks forward to the day when my professional brethren, one and all, will come to look on the Medical Foundation of Epsom College with the same pride of possession as do the great societies that control and endow Tonbridge, Oundle, and other such schools, and I believe that they will help this vision to materialize. I have deliberately avoided allusion to matters of controversy; suffice it to say that if good will and good sense in concert cannot succeed by careful deliberation in determining or developing some *via media* satisfactory to all, I should despair of human nature.—I am, etc.,

August 26th.

RAYMOND CRAWFORD.

### VOLUNTARY BOARDERS IN MENTAL HOSPITALS.

SIR,—The 1922 report of Barnwood House Registered Hospital, by Dr. Townsend, is well worthy of your comment in your issue of August 25th (p. 337), and especially so are his remarks concerning voluntary boarders.

I have for years advocated:

1. That the report of the voluntary boarders for admission should contain the clauses of the Lunacy Act relating to their status, and that they should sign a statement that they have read and understood them.
2. That voluntary boarders should be kept apart from the chronic demented and noisy and dirty patients (I am afraid my experience tells me this is not always carried out).
3. That the period during which the medical superintendent could detain them, after they had given written notice of leaving, should be increased, in order to give adequate time for communication with the relatives.
4. That the Board of Control should be very broad-minded in their views as to "certification or discharge," and especially so with recoverable patients.

The recent suggestions of the Board of Control that voluntary boarders should not be placed under certificates while in residence in the mental hospital are no doubt the result of the well known law case of Miss Lilian Gaul v. St. Andrews Mental Hospital, which was carried to the House of Lords and dismissed in all the courts because the lady had not brought her action within the statutory period. Had she done so I venture a surmise that she

might have obtained a verdict, and then the clauses relating to voluntary boarders might have been amended.

These clauses, if carried out as I have mentioned, and in no way abused, are most excellent, and the history of the cases in Barnwood House, as described by Dr. Townsend, speaks volumes as proof of their kind and successful treatment in this admirable institution. Nothing redounds more to the credit of a mental hospital than the contentment of its voluntary boarders.—I am, etc.,

Bournemouth, Aug. 26th.

LIONEL A. WEATHERLY, M.D.

### HEART DISEASE AND TONSILLAR INFECTION.

SIR,—I read with interest Dr. F. J. Poynton's lecture on the prevention of heart disease in your issue of June 2nd, 1923. Concerning the matter of focal infections which he refers to there are several points which I think might well be amplified.

He remarks that removal of tonsils does not prevent further attacks of rheumatic fever. Here one might suggest that the tonsils are not alone responsible, as focal infections, in the production of rheumatism. Under such conditions the removal of the tonsils will not benefit the case much. The antra and nasal accessory sinuses are not infrequently involved, also the mass of adenoid tissue in the nasopharynx. Again, the tonsils may not have been completely removed, for quite a small piece is sufficient to carry on the infection. Where recurrence has occurred careful investigation would probably have revealed some such condition, as it is not a matter of removing tonsils but of removing the breeding grounds of the organisms and doing away with their portal of entry.

Dr. Poynton is likewise not in favour of removing tonsils in rheumatic children when there is no evidence that they are diseased. The first point is to define what is a diseased tonsil. This, to my knowledge, nobody has been brave enough to attempt. If a mother has infected tonsils, how many months or days will it be before the child's tonsils are harbouring the same organisms?

Because nearly everybody's tonsils contain virulent organisms we have been apt to take it for granted that it is natural they should do so. This has resulted in a popular idea that the functions of the tonsil are to allow certain toxins to pass into the body to help build up its resisting powers. But there is nothing to warrant such an assumption, as people with infected tonsils are certainly not healthier than those without, which they would be if this assumption were true. The removal of tonsils does not lay people open to danger of having their resisting powers lowered, as experience shows us that they are very much improved in health after this has been done.

If, then, it is not the duty of the tonsils to act as a breeding ground for virulent organisms, it is very unwise of us to breed such dangerous things, as we never know the moment when they will turn on us and rend us. Such being the case, is it not better to exterminate, root and branch, such localities? Surely our lives are beset with enough evils without adding the dangerous pastime of seeing who can the longest breed the most virulent strain of streptococci and escape the undertaker. Unfortunately almost the whole population has become infected with certain pathogenic organisms, which are rapidly passed on from parents to children, as under present modes of living it is practically impossible for children to escape infection from their parents.

The appearance of the tonsil has very little to do with its infection, nor has its size. The whole point turns on, Are there any crypts capable of harbouring bacteria? If so, and the child is suffering from some rheumatic infection, failing to find any other possible focus the best treatment would be removal of the tonsils. There is very little risk incurred by so doing, very little inconvenience, and the benefits conferred are usually great.

There is so much hinged on tonsillar infection that a most thorough investigation should be made into the matter, particularly as to the age at which infection of tonsils takes place. Investigations should be made into the infection or otherwise of the tonsils in lower animals as well as the different races of mankind, for it would be interesting

From the figures quoted it would be apparent that an improvement might be looked for in the great majority of cases treated by the "Allen" method, a result quite in accordance with that of all others by whom it had been employed. But while the immediate prognosis was good, experience had shown that in hospital patients the end-results were far from satisfactory. It was rare to find a patient who did not lose ground after discharge from hospital. Almost all who had been readmitted had shown a distinct loss of weight and a decreased carbohydrate tolerance, not infrequently accompanied by thirst, polyuria, etc. Unwillingness to adhere to the diet was responsible in many cases; but an inability to understand the rationale in some and the conditions of life, particularly at the present day, in others made it very difficult, even for those who were most anxious to "keep well." Among private patients the prognosis was, of course, much better. It should be remembered that it was necessary to insist upon these patients reporting for examination from time to time. It was not uncommon for a zealous patient grossly underfeeding himself without regard to his general condition in an endeavor to remain sugar- and acetone-free at all costs. One patient, a woman of 55, who had been under treatment two years before good results carried on an unaided unit until six months ago, when a recent but persistent cough and spitting again brought her under observation. She confessed to long periods of semi-starvation with deliberate loss of weight, but she was proud of the fact that she had remained sugar- and acetone-free. The general condition had greatly deteriorated and there was an obvious tuberculous lesion at the right apex.

5. Insulin.—Ten cases had been treated with insulin and the result in each case had been a distinct improvement. All save two were cases of severe prolonged diabetes. With one exception they had all originally intended to put each patient upon what had been his optimum diet within last dismissed from hospital, but all had retrogressed considerably and this proved could not be followed in this way. Four cases, however, commenced treatment in this way, but in each case it was found that there was a considerable reduction in the carbohydrate tolerance, much sugar in the urine, some acetone and a high blood sugar. All had lost weight. An effort, not always successful, was made to render each sugar-free by starvation methods and thereafter to work up to what was considered a sufficient diet, using insulin to keep the patient sugar-free. The method adopted in determining the requisite sugar-free diet was calculated in each case. A chart showed the effect of such a meal—carbohydrate 20, protein 18, and fat 25—upon the blood and urinary sugar curves obtained by hourly estimations in (1) a normal individual, (2) a diabetic without insulin, (3) a diabetic with insulin, in that particular instance 10 units. The fall in the curves was very striking. This method of treatment was most suited to chronic cases with a low carbohydrate tolerance. These patients were kept under their best weight and the blood sugar tended to run above normal limits. Two patients, adjudged to be cases of comparatively recent origin, were treated on the usual "Allen" lines, but the carbohydrate tolerance was low and acetone readily appeared in the urine. Sufficient insulin was given to keep the patient's sugar- and acetone-free with a normal morning blood sugar and at a reasonable weight. This method, on the lines of that described recently by Graham and Harris, seemed to be most satisfactory in "early" cases. Four cases showed so pronounced a degree of acidosis that insulin administration with abundant carbohydrate had to be commenced at once. In these patients the urinary sugar was entirely disregarded during the earlier treatment, attention being directed to the urinary acetone and diacetic acid, the alcohol "CO" and the ammonia-nitrogen ratio. Large doses of insulin, 40 to 60 units in the day, were given, the results being controlled by blood-sugar estimations 3½ to 4 hours after injection.

In no case did any untoward symptoms follow such doses at this stage of treatment, and it would appear that so long as sugar and acetone were present in the urine the estimation of the blood sugar was unnecessary. When rendered acetone-free the treatment of these patients followed lines similar to that of those described above. All patients treated by insulin increased in weight, the gain varying from 1 to 8 kilograms. All showed a very definite improvement in general condition, mental as well as physical. In all save one case, sugar and acetone rapidly disappeared from the urine, the acetone sometimes with dramatic suddenness. The exception was a man admitted with marked acidosis, to whom insulin was given in large doses, but the urine was not rendered acetone-free for twenty-one days nor sugar-free for thirty-eight days. Attempts subsequently to reduce the dose of insulin in that case had always been followed by a return of sugar and acetone to the urine. He would appear to have no pancreatic tissue capable of recovery. A typical result of treatment was illustrated by another chart, which represented the later period of residence of a patient who on admission had shown 85 grams of sugar, much acetone and diacetic acid on a diet of carbohydrate 60, protein 25, and fat 5; he weighed 51 kilos. With an initial dose of 30 units of free and acetone-free for twenty-two days upon carbohydrate 50, protein 60, and fat 100. During that time blood sugar fell from 0.55 per cent. on admission to 0.10 per cent. fourteen days later, and thereafter the pre-breakfast blood sugar remained within normal limits. The dose of insulin was reduced to a single morning dose of 5 units upon an unchanged diet, but at that point the patient began to add unauthorized carbohydrate to his diet, and sugar appeared in the urine. Home circumstances compelled him to leave hospital, but subsequently he was able to continue on a diet of carbohydrate 80, protein 80, and fat 100, with a weekly starve day, without insulin, sugar- and acetone-free. His weight on dismissal was 52 kilos. The chart showed an undoubted increase in carbohydrate tolerance as the result of insulin treatment. It might be argued that a similar result could have been obtained in this case by treatment alone, but on previous admissions the patient had shown a decreasing carbohydrate tolerance and a general downward tendency. So satisfactory a result would have been most improbable.

The effect of insulin had been to allow restoration of pancreatic function, but this would seem to occur not only in cases treated on low diet and with a normal blood-sugar level, but also in those for one reason or another were given a full diet with larger doses of insulin and in whom the blood sugar was above normal. He had seen this strikingly illustrated in one private case so treated in which symptoms of hypoglycæmia had led to a gradual reduction of insulin dosage without increased urinary sugar and with very considerable general improvement. The morning blood sugar in this case was 0.18 to 0.22 per cent. and the diet had remained unchanged. A third chart contrasted the results of "Allen" and insulin treatment in a telegraph boy, aged 13, first admitted three years before. The acetone, blood sugar, urinary sugar, weight, and dismissal diet were characterized in that order. It would be seen that the first period of treatment was very satisfactory. The second period, two years later, was not so good, although the urine was rendered sugar- and acetone-free and the patient gained slightly in weight; but the dismissal diet did not equal that of two years previously in a growing boy. The carbohydrate tolerance, too, had considerably decreased. His third stay in hospital six months later was entirely unsatisfactory. It was now found impossible to prevent his adding to his diet, and he was dismissed irregularly with acetone and sugar in the urine and his carbohydrate tolerance never discovered. In March of this year the patient was readmitted to hospital. The blood sugar, however, was brought below 0.15 per cent. He was now 16 years old and terribly emaciated, weighing only 24.5 kilos (52 st. 11 lb.). The blood sugar was 0.5 per cent. The urine contained acetone and diacetic acid and was loaded with sugar. He was incapable of moving himself in bed, all the reflexes were absent, and the skin was so tightly stretched over the bones that great difficulty was experienced in inserting the comparative

Space will not admit of a detailed description of how the brush should be used; it is enough to say that its stroke should be applied in the long axes of the teeth as one would brush the teeth of a comb, beginning on the gum margin, and that the brushing should be applied as carefully on the lingual as on the buccal surfaces of the teeth, the bristles being pushed between the teeth from inside and from outside to reach the interdental papillae. A dentifrice is of little importance in comparison with friction. Common salt is the oldest in the world and probably remains the best, but to keep the teeth clean, especially in the mouths of smokers, the occasional use of some paste or powder is a necessity. The tooth-brush, properly used, I believe to be the most powerful weapon we possess to-day in our fight against two diseases which are among the most prolific causes of ill health among civilized man.—I am, etc.,

London, W., Sept. 3rd.

#### ACIDOSIS AND ACIDAEMIA.

SIR,—Dr. Cammidge's paper on acidaemia (August 25th, p. 318) is of great interest, and will go far to dispel the idea that the presence of acetone is indicative of acidosis.

The majority of children suffering from any febrile disease excrete acetone in their urine, and it seems probable that it is a more or less constant product of bacterial invasion in childhood.

If the measure of acidaemia is the amount of sodium bicarbonate required to alkalinize the urine, the test is surely of no clinical value. Dr. Cammidge gives half a gram per kilo of body weight as the necessary amount.

In a man of 10 st. this would involve a dose of 32 grams—more than an ounce—and for a baby of 11 lb. nearly 40 grains. Such doses are impracticable. They would need eleven times as much water to dissolve them, and they might have to be doubled. Less than a twentieth part of these doses of potassium bicarbonate is all that is necessary to render the urine strongly alkaline. Would not this drug be much more effective in neutralizing an acidaemia?—I am, etc.,

London, E., Aug. 25th.

A. CAMPBELL STARK.

#### ETHER VERSUS CHLOROFORM.

SIR,—The correspondence on this subject could perhaps be prolonged with advantage because any advance in general abdominal surgery in adults is likely to be due in great measure to the work of anaesthetists. During my short experience as anaesthetist, involving some five thousand cases of general anaesthesia, it often seemed to me that the increased risk of complications arising from the use of ether was more than counterbalanced by the increased facilities obtainable surgically with chloroform. At that time open ether was just coming into extensive use in this country, but the semi-closed methods had not been employed to any great extent. Gas and oxygen, combined with suitable muscular relaxants, had not been employed, or not employed extensively in general abdominal work, so that I was unable to have any experience of it.

It will be generally admitted that with the exception of certain fracture cases, deep muscular relaxation is not required in operations on the limbs, nor in cranial, neck, or thoracic cases, so that in these almost any suitable method may be used. The question of muscular relaxation, to which I wish mainly to refer, relates to abdominal and perineal operations, and also includes the setting, extension, and completion of splintage in fracture cases. In the usually simple and rather mechanical procedures of most such operations it rests with the anaesthetist rather than with the surgeon to secure efficiency. When relaxation is good anyone of average ability and practice can do the operation with some degree of efficiency and speed, but when relaxation is bad no one can do it properly. For instance, I have had my hand so tightly gripped in a loin incision for nephrotomy that I could not remove it without tugging, and I have seen the sac of a left femoral hernia come down into the wound a further one and a quarter inches as relaxation progressed. Had this last operation been completed without relaxation being attained the whole

of the sac would not have been removed and any recurrence of the hernia might have been attributed to non-employment of some special technique. Conversely credit does not belong to the anaesthetist in a gall-bladder case if the liver happens to be of the type that with rotation can be drawn out of the abdomen, or in a case if the kidney has a long pedicle and is non-adherent but in the ordinary operations on these organs good muscular relaxation is essential.

The chief disadvantage of the etherized patient from surgeon's point of view is that a really first-class, degree of complete muscular relaxation is seldom attained. That it may be attained by relatively inexperienced ministrators is well known, though it cannot be achieved with sureness by the experienced. The muscles of etherized patient almost always have a marked degree of tone. This may render a systematic examination of abdominal contents through an incision just large enough to admit the hand difficult. Under these conditions efficient closure of the wound may be a lengthy and tiresome process, with a correspondingly increased liability to ventral hernia or to adhesion of the omentum or intestines to the scar, and with a distinct element of risk to operator and his assistant from a needle prick in a severe case. Increased haemorrhage also may be a minor disadvantage of the administration of ether, from vasodilatation or from respiratory obstruction causing slight cumulative cyanosis; but with the modern types of incision a discount is necessary for the increased blood supply which they carry and also for any degree of inflammation that may be present. In intracranial operations increased haemorrhage or congestion may cause great difficulty. The seems to be a greater difficulty in maintaining a free, noiseless airway with ether than with chloroform, even when atropine has been given.

Until large figures for the bronchitis rate taken post-operatively for ten days by independent observers in different institutions are available we cannot assess the risks. I believe them to be much greater than is generally supposed.

When anaesthetists are prepared to measure muscular relaxation scientifically by means of a tonometer they will be able to improve greatly the purely surgical side of the matter. Such a tonometer could be made part of a wound retractor or could be adjusted on a limb away from the site of operation. Readings would be required for the different stages of the operation and the device would be of immense advantage to the anaesthetist himself. One practical way of estimating a medium degree of relaxation at the close of an operation is that in the absence of inflammation a continuous suture through the peritoneum and posterior sheath with a round-bodied needle just does not cut out as it is pulled taut.

There is a danger of the art of chloroform anaesthesia being lost. The student is taught it less and less and perhaps is overwarned of its dangers. Often chloroform is the method of choice, especially in outlying districts, or in certain operations involving a large exposure of a surface likely to ooze such as in a radical operation for carcinoma of the breast. Apart from spinal analgesia there is no greater degree of operative comfort to be obtained than by a skilled chloroform administration uncomplicated by any other drug. The slight degree of abdominal movement, the absence of excessive haemorrhage, and the high degree of muscular relaxation all materially shorten the operation and enable completeness to be attained. Any operator of experience knows that under these conditions the abdominal contents can be examined with ease and the abdominal wall can be accurately sutured in layers with considerable speed, whereas when the conditions are modified the process may become lengthy, tiring, and likely to cause shock.

It is a question how far the supposed increased risk, if any, from chloroform when given by an expert is operative in a patient whose lungs and heart are sound and in whom the airway is clear, especially if oxygen is given at the same time. In bad obstruction cases regurgitation may occur with any anaesthetic, even quite shortly after stomach lavage. Other risks such as rupture of an empyema

necessary at the outset of treatment. When two doses a day were required the larger should be given in the morning; the ideal dose just corrected the deficiency. It was easier to maintain the balance in long-standing elderly diabetics than in recent cases of the disease in young people. An attempt should be made to maintain the blood sugar at a normal level; a raised blood sugar furnished a stimulus to the pancreas and was to be avoided. When a patient was discharged from hospital in Toronto a long detailed letter was sent to the family physician, but by the time the patient left hospital he was thoroughly fit and fat with the routine. The symptoms of hypoglycæmia included a feeling of uneasiness of impending disaster and trembling, incoherent speech, sleepiness, and hunger. In children, pallor, a rise in pulse frequency, and sweating were common. The rate of fall of blood sugar was potent in determining the onset of symptoms, which might not occur until the blood sugar reached 0.60 per cent., but it had been recorded as low as 0.082 per cent. before symptoms appeared. If the patient was comatose from an overdose of insulin consciousness was usually restored in two minutes by 10 to 15 minims of adrenaline, given subcutaneous, adrenaline having the power of rapidly turning on glycogen from the liver. When consciousness was restored by this means 10 to 20 grams of glucose might be given by the mouth. Insulin kept at room temperature retained its potency for at least six months, but Dr. Banting had no knowledge as to the effect of the Indian climate on its activities. He said that there was no reason why diabetic patients should not be treated as well by the general practitioner as the specialist.

# SECTION OF VENEREAL DISEASES.

Sir Archibald Reid, K.B.E., M.B., President.

## DISCUSSION ON PREVENTION AND TREATMENT OF CHRONIC GONOCOCCAL PROSTATITIS AND FISTULITIS.

### OPENING PAPERS.

I.—KENNETH M. WALKER, F.R.C.S.,  
Lecturer in Venereal Diseases, St. Bartholomew's Hospital; Surgeon in Charge of Genito-Urinary Department, Royal Northern Hospital and Miller Hospital for South-East London.

In opening this discussion I do not propose to deal methodically with the routine treatment of this condition nor to discuss matters on which we are probably all agreed, but rather to select certain points which I believe to be important ones, and which I hope may furnish material for an interesting discussion.

No one will deny that the subject to which we are devoting our attention at this year's meeting of the Venereal Diseases Section of the British Medical Association is of the very greatest importance, not only on account of the complications which may arise during the course of a chronic prostatitis, but also because of the difficulties which we encounter in its treatment. The prostate furnishes for organisms an easy gate of entry into the blood stream, with the result that practically any structure in the body may become the seat of a metastatic lesion. Personally I am of the opinion that from an infected prostate a spread of organisms may take place by means of the lymphatics as well as by means of the blood stream. This opinion is based on an investigation I carried out a year ago on the subject of the lymphatic spread of infection after the operation of prostatectomy. By cutting sections and staining for organisms in the tissues I was able to trace following the infecting organisms from their point of entry in the lymphatic spaces of the prostate capsule to their arrival in such situations as the epididymis, the periteneal lymphatics, and the capsule of the kidney. While not wishing to suggest that the patient who has been left with a torn and infected capsule after the operation of prostatectomy is entirely comparable to the patient suffering from a chronic prostatitis, I think that the analogy is sufficiently

close to render it probable that in addition to the spread of infection from an infected prostate by means of the blood stream infection may also be carried by the lymphatics. This spread, as we all know, is particularly common in the direction of the epididymis, but I believe that if a careful look-out be kept in all cases of prostatitis it will be found that infection of other portions of the genito-urinary tract is not so uncommon as is sometimes presumed. For example, made in all cases of chronic prostatitis renal casts will not infrequently be found for a short period of the disease, indicating that a transient infection of the kidney has occurred. This infection is rarely gonococcal but due rather to secondary organisms. Chronic prostatitis, as the title of the subject for this year's discussion suggests, is almost invariably associated with a certain degree of infection of the vesicles. In this connection I should like to point out an error in diagnosis which I believe to be a common one, and that is the error of labelling what is mainly a case of vesiculitis one of prostatitis. This mistake is in great part due to the anatomy books, in which the vesicles are described as two obliquely placed sacs that start at the mid-point of the upper border of the prostate, and pass upwards and outwards at an angle of from 50 to 45 degrees to the horizontal. A dissection of half a dozen bodies in the post-mortem room will be sufficient to convince anybody that the vesicles do not occupy the oblique position generally ascribed to them, but are horizontally placed organs lying along, and for the most part in intimate contact with, the upper border of the prostate. As a result of this close relationship with the prostate it is extremely easy for the examining finger to mistake the induration of a vesicle for an induration of the upper part of the prostate, and I have frequently found cases diagnosed as chronic vesiculitis which in my opinion were clearly cases of chronic prostatitis. Fortunately the treatment of the two conditions is in the main the same, so that the error in diagnosis is not of such importance as it otherwise would be.

### TREATMENT.

I suppose that we are all agreed that of the therapeutic measures available for the treatment of chronic prostatitis the most important, so that I may be pardoned if I dwell at some length on this subject. Massage of the prostate from the rectum achieves three objects:—1. It empties the prostate follicles of inflammatory products, and thus assists in the drainage of that organ. 2. It brings fresh blood and lymph to structures that are the seat of chronic inflammation, and hastens processes of repair. 3. It drenches the blood stream with antigen and provokes a reaction similar to that produced by the injection of a vaccine. As these points are of the greatest practical importance in the treatment of chronic prostatitis they will be considered in further detail. I believe that it is generally supposed that the action of prostatic massage in emptying the prostatic follicles is a direct one—that is to say, that the finger directly expresses the accumulated contents of the gland. However, I am one of those who subscribe to the view that this is not the case, but that the emptying is mainly accomplished by the contraction of the muscle fibres surrounding the follicles. These prostates is a gland remarkably rich in muscle fibres. The glands are arranged circularly around the fundus of the prostate and longitudinally in the neighbourhood of its duct, so that they are ideally disposed for the emptying of the gland. The fact that the muscle of the prostate is stimulated by the massaging finger is sometimes shown clinically by the sudden hardening of the prostate that is felt during massage. It is obvious that emptying of the glands will be accomplished much more effectively by the co-operation of the muscles than by the mere mechanical pressure of the massaging finger, and for this reason the question of whether the muscle of the prostate contracts during massage is not one of merely theoretical interest. Emptying of the follicles is best accomplished by the action of the prostatic muscle, one is tempted to speculate whether a stimulus cannot be employed that is more effective than this. I do not refer to such

June 2nd. The mouth could not be opened to its full extent until June 15th, and a quite perceptible "risus" continued till about this date. The neck muscles also remained hard, and the gait on walking was stiff and constrained for more than six weeks.

Tetanus fortunately is not common in civil practice, considering the number of wounds of daily occurrence in which there must be a risk of infection. Its unexpected onset after a trivial wound, the dramatic symptoms, the dread so evident in the mind of the patient, the dismay of the relatives, and the frequently fatal result make up a combination which taxes at the time one's resources to the uttermost, and leaves a lasting impression on the memory.

Theoretically every patient who suffers from a soiled or lacerated wound should be injected with a prophylactic dose of tetanus antitoxin as a matter of routine, and as is the practice in military service in time of war; but in civil practice, when the risk of infection may appear to be slight, one is apt to trust to a careful disinfection of the wound, and spare the patient the pain, trouble, and expense of the injection, the annoyance of the subsequent rash, and the possible risk of anaphylaxis should serum have to be employed at a later date for some other infection—for example, diphtheria. Is it justifiable to take this risk?

If unfortunately infection has occurred, at the earliest onset of any suspicious symptom antitoxin should be injected and pushed to extreme limits. In this case I used 88,500 units in the course of nine days, with no untoward results except the rash. The supposed advantage of intrathecal injection must be balanced against the risk and disturbance of the necessary anaesthetic. Chloroform had to be given freely to obtain sufficient relaxation of the spinal muscles, and the first and most violent convulsion occurred immediately its administration was stopped. Morphine gr. 1/4 subcutaneously every four hours was far more effective than chloral and bromide given by rectum in controlling spasms and inducing sleep. Constipation was a marked feature throughout. The catgut used in suturing the wound was at my request examined bacteriologically, and found to be sterile.

It would be interesting to hear the views of those with experience of tetanus:

1. As to the routine use of prophylactic injections of antitoxin in all soiled wounds, slight or otherwise.
2. The advantages of intrathecal as opposed to intramuscular injection of the antitoxin, and the dosage and length of time during which the injections should be continued.
3. The incidence of tetanus in special districts—for example, certain parts of Essex, from which several cases have lately been reported.

In conclusion I must add that the recovery of this patient was chiefly due to the devotion and resourcefulness of her two nurses, Miss Tillot and Miss Thompson, to whom it is impossible to be sufficiently grateful.—I am, etc.,

Wimbledon, Aug. 27th.

JOHN A. HAYWARD.

## The Services.

### DEATHS IN THE SERVICES.

Surgeon Major Thomas Beard Farncombe, Bengal Medical Service (retired), died on May 16th last. He was the son of George Farncombe, was baptized at Bishopston, Sussex, on August 4th, 1830, and took the M.R.C.S. in 1851 and the L.S.A. in 1852, over seventy years ago. Entering the I.M.S. as assistant surgeon in February, 1854, he became surgeon-major in 1873, and retired in February, 1875. He served in the Sonthal insurrection of 1855-56, and in the Bhutan campaign on the North-East Frontier of India in 1865-66. At the time of his death there were only two officers senior to him on the retired list of the I.M.S., the late Surgeon-General Sir Benjamin Simpson, who died on June 27th last, and who, though senior in rank and length of service, was several months younger, and Deputy Surgeon-General Clarence Cooper.

Lieut.-Colonel Henry Armstrong, Madras Medical Service (retired), died at Thun, Switzerland, on August 14th, aged 68. He was born on October 29th, 1854, educated in Dublin, and took the L.R.C.S.I. in 1877 and the L.K.Q.C.P. in 1878. He entered the I.M.S. as surgeon in March, 1878, became lieutenant-colonel after twenty years' service, and retired on June 30th, 1908. He served in the Rumpa rebellion of 1879-80, in the Afghan war in 1879-80 (medal), and in the China war of 1900 (medal).

## Obituary.

### ERNEST FRANCIS BASHFORD, O.B.E., M.D.,

Adviser in Pathology, British Army on the Rhine; formerly Director of the Imperial Cancer Research Fund.

WE regret to record the death of Dr. E. F. Bashford, which took place suddenly from heart failure on August 23rd at Manderscheid, Eifel, Germany.

Ernest Francis Bashford was the eldest son of William Taylor Bashford, and was born at Bowdon, Cheshire, in 1873. He was educated at George Heriot's School and Edinburgh University, graduating M.B., Ch.B. in 1899, and M.D. (with gold medal) in 1902, after a very distinguished academic career. He had been Vans Dunlop Scholar in anatomy, chemistry, zoology, and botany, Mackenzie Bursar in practical anatomy, Whitman Prizeman in clinical medicine, Houldsworth research scholar in experimental pharmacology, Stark Scholar in clinical medicine and pathology, and Pattison Prizeman in clinical surgery. After graduating he travelled to Germany as holder of the McCosh Scholarship for study and research in the medical schools of Europe. At Berlin he studied bacteriology and pharmacology; later he was awarded a Grocers' Research Scholarship and studied at Frankfurt under Professor Ehrlich at the Institute for Experimental Therapeutics. For a short period he was assistant to Professor Liebreich in the Pharmacological Institute of Berlin. In 1901 he won the Milner Fothergill Gold Medal in Therapeutics of the University of Edinburgh, and returned in the following year to Edinburgh as assistant to the late Sir Thomas Fraser. While there Bashford published his well known monograph on the pharmacological antagonism of atropine and morphine.

In 1902 he was appointed director of the newly founded Cancer Research Fund, a position which he held till 1914, when he resigned through ill health. During these twelve years he held a prominent position in cancer research in this country and on the Continent, and built up the organization of the Imperial Cancer Research Fund as an experimental research institute. He was president of the International Congress on Cancer held at Heidelberg in 1906. His work at the Imperial Cancer Research Fund will best be remembered by the numerous contributions on the zoological and ethnological distribution of cancer, national and hospital statistics, the phenomena of transplantability of animal tumours and the induced resistance to them. Into the controversies which raged around these topics he threw himself with enthusiastic energy.

Bashford served in the R.A.M.C. from 1915 till the end of the war, first in the Mediterranean Expeditionary Force, then in France, and afterwards in the Army of Occupation, holding the post of adviser in pathology up to a few months before his death. He was mentioned in dispatches and received the O.B.E. He leaves a widow and one daughter, to whom the greatest sympathy will be extended by all who knew him.

We are indebted to Dr. ARCHIBALD LEITCH, Director of the Cancer Hospital Research Institute, for the following appreciation:

Though he gave up cancer research nearly ten years ago we are saddened by the news of Bashford's death. As a comet suddenly appears out of space, blazes gloriously across the sky, and fades rapidly out of sight, so did that forceful and brilliant and wayward personality impress us. It is true that he had considerable experience of medical research in Edinburgh, Frankfurt, and Berlin, but when he was chosen to be the first superintendent of the newly instituted Imperial Cancer Research Fund he was a young man almost wholly unknown, and certainly untried in the responsibilities of such an office as he was to occupy. But the choice of the selection committee was superlatively justified by the results he was to achieve. Speaking from an imperfect book acquaintance with the state of cancer research at the time, I should say that the outlook was not hopeful; the solid work of pathological anatomy and histology had been completed to the limits of usefulness, the chemistry and biochemical investigations of tumours offered little scope, the exploration of numerous hypotheses was

the operation of proctotomy. Exactly why the incision of inflamed tissues should bring about a cure may not be readily explicable, but incision undoubtedly has a place, although a very small place, in the treatment of chronic proctitis. In three out of the five cases referred to a small pocket of pus was found in the substance of the prostate, and the beneficial action of drainage was easily explained.

CONCLUSIONS.

Before I close I would again draw attention to the fact that in the preceding remarks I have not attempted to summarize the treatment of chronic proctitis, but have contented myself with bringing forward certain points which I hope may serve as a basis for a discussion. I am fully aware of the fact that I have not even mentioned such important subjects as the prevention of prostatitis, the avoidance of complications, and the general treatment of the patient. Nor have I touched on that vital question, the standard of cure—a question that is certainly of paramount importance and one on which I shall look forward to hearing others speak. I have long been convinced that the value of these meetings lies in the discussion that follows rather than in the introductory paper, and I am sure that this year's meeting will prove no exception to the rule.

II.—DAVID WATSON, M.B., C.M., CLAS.,  
Lecturer on Venereal Diseases, Glasgow University; Surgeon,  
Glasgow Lock Hospital; Surgeon, Venereal Department,  
Glasgow Royal Infirmary.

GONOCOCCAL VESICULITIS.

My duty to-day is to introduce the subject of the prevention and treatment of gonococcal vesiculitis. The question of primary urethral infection. If infection of the vesicles occurs after treatment has been begun, that method of treatment has failed in one of its essentials—namely, in the prevention of complications. It is therefore necessary to discuss the principles involved in the local treatment of gonococcal urethritis.

Let us consider first those cases which come under treatment apparently before infection of the posterior urethra has taken place. We are at once faced with the important question, are we justified in relying upon local treatment applied only to the anterior urethra? Two main difficulties seem to me, prevent us from following that course. First of all, there is always some uncertainty as to the freedom of the posterior urethra from infection. There is an incubation period after implantation of the gonococcus in the posterior urethra, during which no recognizable signs present themselves. By the time pus is present in quantity sufficient to show in the second urine glass, a posterior urethritis is well established, and quite possibly the gonococcus is already within the vesicle. Then again, are we aware of any method of purely anterior treatment which not only will cure an anterior urethritis but will prevent backward spread? I cannot say that I am. It is always with reluctance and only when forced by the patient's circumstances that I prescribe treatment limited to the anterior urethra. While being untreated, the risk of complications is increased. Prevention of vesiculitis is, to my mind, prevention of the posterior urethritis, and then, the posterior infection of the posterior urethra, in which it fails to prevent infection is successful in the majority of chosen cases, there is a considerable percentage in which it fails to prevent infection.

Prevention of vesiculitis is, to my mind, prevention of the posterior urethritis, and this I believe can be ensured once the anterior urethra has become infected only by local measures. In an acute case, rest in bed is essential. Hot sitz baths and hot rectal irrigations are useful for their sedative effect, for relieving pain in the early stages, and also for promoting absorption in the later stages. Diathermy is perhaps the most useful of all methods of treatment. Atropine as a sedative and as a prophylactic to prevent extension to the other vesicle or to either epididymis is also indicated. Vaccines as ordinarily prepared I have found more frequently to be harmful than helpful, but the detoxicated vaccines now available I believe may be used with safety, and occasionally they seem to be beneficial. Antigonoococcal serum appears to vary in their qualities and to give unequal results.

every twenty-four hours in the greater concentration. My own preference, both from laboratory and clinical experience has taught me that if this treatment is properly carried out and if the patient follows instructions as to general conduct, extension of the infected area can be prevented almost with certainty, and that a posterior urethritis with its risk to the vas and vesicle will not occur.

It is true that *grand lavage*, in spite of previous clearing of the anterior urethra, gonococci would probably be carried into the posterior urethra and intimately mixed with a gonococcal solution, and the great majority, if not all of them, will be expelled when the bladder is emptied as the end of the treatment. Should any gonococci remain within the posterior urethra, they are in contact with a mucous membrane saturated with a solution which both expectorates and expels the growth of the gonococcus. The clinical test is, however, the crucial one, and experience has proved not only that *grand lavage* is safe in use but that it is the most effective treatment for an anterior urethritis and that it acts as a preventive of posterior urethritis.

Now to consider those cases of gonococcal urethritis which come under treatment after infection of the posterior urethra. I think there is little difference of opinion as to the method of treatment to be adopted. *Grand lavage* is indicated in all except in hypertensive cases. But we can have no assurance that the gonococcus is not already within one or both common seminal ducts, and possibly beyond the reach of the irrigating fluid. It was shown by Low and Oppenheim that reversed peristalsis along the common seminal duct and was deferred, induced by local excitation of the posterior urethra, is the means by which infection usually reaches the vesicles and epididymis. Infection of the vesicles through the lymphatic or circulatory system is possible, but must be relatively uncommon.

Protection of the whole region from any transmigration is therefore most important. No treatment involving the passage of any urethral instrument is permissible in acute urethritis. The only exception is in retention of urine which cannot otherwise be relieved, and then special precautions must be observed. Rectal examinations must be conducted with the utmost gentleness. The patient must be impressed with the need for protection of the perineum and scrotum from the slightest injury, and should be advised to rest as much as possible. A run on a motor cycle, or any similar excitation, is almost certain to result in conversion of infection along the seminal duct. In addition to rest, I think atropine is of distinct value. Schindler proved that the tendency to reversed peristalsis can be inhibited by the use of atropine, and insertion into the rectum night and morning of a suppository of 1/100 grain of atropine has for some years been my routine practice in all cases of posterior urethritis. I have now much confidence in relying on the atropine to prevent complications. I find almost invariably that where vesiculitis or epididymitis develops in cases under treatment the use of the atropine suppositories for one reason or another has been neglected. To recapitulate, the main point in prevention of vesiculitis is the adoption of a suitable treatment for the urethral infection, and in my experience the best has proved to be *grand lavage* with 1 in 4,000 acridianum combined with the use of atropine, and, of course, protection from injury. As to the treatment of vesiculitis, the means at our disposal may be divided into expectant and operative measures. In an acute case, rest in bed is essential. Hot sitz baths and hot rectal irrigations are useful for their sedative effect, for relieving pain in the early stages, and also for promoting absorption in the later stages. Diathermy is perhaps the most useful of all methods of treatment. Atropine as a sedative and as a prophylactic to prevent extension to the other vesicle or to either epididymis is also indicated. Vaccines as ordinarily prepared I have found more frequently to be harmful than helpful, but the detoxicated vaccines now available I believe may be used with safety, and occasionally they seem to be beneficial. Antigonoococcal serum appears to vary in their qualities and to give unequal results.

way, all of which he was enabled to surmount. Dr. Masterman, with his long experience in Jerusalem, knew Dr. Torrance well and bears high testimony to his professional skill and his missionary qualifications. As a surgeon he was particularly successful and always kept abreast of the times; before the war he was regarded as one of the leading surgeons in the Near East. The onset of war with Turkey meant the break-up of his work, as of all missions in Palestine, and Torrance did valuable service at home in the R.A.M.C., being in charge of a Scottish hospital with the rank of major. On his return to Palestine he was able once more to reopen his hospital, and was awarded the O.B.E., a recognition by those in authority of the great value of his work.

The sudden death of Dr. CLARENCE ROBINSON from angina pectoris while on holiday at Ramsey, Isle of Man, on August 29th, caused much sorrow in the Warrington district. Dr. Robinson was a native of Cork, and received his medical education there; he took the diplomas of L.R.C.P. and L.R.C.S.I. and L.M. in 1903. He was for a time house-surgeon at the Ramsgate Infirmary, and afterwards visiting surgeon to Ramsgate and St. Lawrence Dispensary; subsequently he was for nearly two years in practice at Camberwell Green. In 1908 he took over a practice in Latchford, Warrington, near the Cheshire boundary, and very soon his professional skill and assiduity built up an extensive practice. He became an honorary surgeon to the Warrington Infirmary, and his skill as an operating surgeon was recognized by his colleagues. He was also surgical specialist to the Warrington Pensions Board. During the war he acted as a visiting surgeon to the Lord Derby War Hospital and to the Red Cross Hospital at Thelwall Heyes. He was a loyal member of the British Medical Association and of the Warrington Panel Committee. Dr. Robinson has been cut off suddenly in the prime of life—he was only 42—and in the height of success, and much sympathy has been extended from all classes to his widow and her two sons.

Dr. WALTER SMITH CHEYNE, V.D., died in Aberdeen on August 19th, aged 70, having been taken ill while on holiday at Dinnet, on Decside, and removed to his home. He was born in Aberdeen, and educated at Stevenson's School, Aberdeen, and at the grammar school and university of that city, where he graduated as M.B. and C.M. in 1876, and as M.D. in 1884. He started in practice in Aberdeen in 1882, and at the same time joined the old Volunteer Force as surgeon, serving first in the Volunteers and later in the Territorial Force, up to 1916, when he retired in the rank of colonel. During the recent war he served as medical officer in the Highland branch of the R.F.A., and later in the Aberdeen Volunteer regiment. He received the Territorial Decoration in 1901. Dr. Cheyne was a member of the Aberdeen Division of the British Medical Association. He is survived by three daughters and one son, Captain D. G. Cheyne, M.C., R.A.M.C.

Dr. RIDLEY MANNING WEBSTER died on August 30th at Ealing, where he had resided since 1901. He was born in London in 1847, entered the Middlesex Hospital as a dental student in 1868, and duly qualified as L.D.S. Eng. Relinquishing dentistry, he took up medicine in 1874, and obtained the diplomas of M.R.C.S. Eng. and L.S.A., and later L.R.C.P. Edin. In 1881 he held two resident appointments at the Middlesex Hospital, under the late Drs. Cayley and Hall-Davis, and then settled at Muswell Hill, where he established a large practice and gained a high reputation as a medical practitioner. In 1884, under the stress of professional work, he contracted pleuropneumonia, from which he never really recovered, for it left him with the remains of an empyema, and a recent perforation of a crippled lung led to septic bronchitis. In 1900 he had the misfortune to fracture a patella, and as some disability following a delayed recovery he relinquished practice. A colleague, H. A. S., writes: Dr. Webster was a many-sided man, for beyond his professional gifts he was a naturalist, a skilled mechanic, an antiquary, and an authority on church architecture. A Cartesian in search

of truth, though silent as to nature's mysteries, in his broad outlook he was a humanitarian, altruistic, humble, and self-denying. He did good work for the St. John Ambulance Association, and he was a member of the British Medical Association and of the North London Medical Society. He never married.

Dr. ALAN EVERLEY TAYLOR, surgeon of the s.s. *City of Calcutta*, died of heart failure after heat-stroke, at sea, towards the end of August. He was the son of Dr. Everley Taylor, of Langholm, Dumfriesshire, late of Scarborough, and was educated at Oxford, where he graduated as M.A., M.B., and B.Ch. in 1910, and at the Universities of Göttingen and Leeds. After graduating he filled the posts successively of house-surgeon, house-physician, and resident ophthalmic officer of Leeds General Infirmary. He took a temporary commission as lieutenant in the R.A.M.C. on December 28th, 1914, was promoted to captain after a year's service, and served as officer in charge of Ophthalmic Centre No. 82.

## Universities and Colleges.

### ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.

#### Parkin Prize.

In terms of the bequest made to the College by the late Dr. John Parkin, a prize of the value of £100, and open to competitors of all nations, is offered for the best essay, "On the curative effects of carbonic acid gas or other forms of carbon in cholera, for different forms of fever and other diseases." Essays (written in English) must be received by the secretary not later than December 31st, 1923. Each must bear a motto, and be accompanied by a sealed envelope bearing the same motto outside, and the author's name inside. The successful candidate must publish his essay at his own expense, and present a printed copy of it to the College within three months after adjudication.

### CONJOINT BOARD IN IRELAND.

The following have been approved at the examination indicated:

**FINAL PROFESSIONAL.**—Jane A. Brennan, F. S. Bourke, H. Bugler, P. J. Clarke, S. L. Christie, S. B. Carlisle, Dorothy M. Coulson, S. H. Ervin, F. B. Harrison, P. Kilcoyne, P. S. McCabe, P. J. C. MacDonnell, Iris P. Nelis, Mary R. Nolan, T. V. C. Nolan, D. M. F. O'Connor, J. F. O'Connor, Anne O'Connor, A. T. O'Grady, C. B. D. O'Hanaghan, Helen P. Regan, Mary A. Ryan, J. D. Sayers, R. E. Sadlier, S. L. Simon.

### SOCIETY OF APOTHECARIES OF LONDON.

The following candidates have passed in the subjects indicated:

**SURGERY.**—E. N. C. Annis, E. E. E. Attale, A. Cawadias, H. S. Chadwick, H. T. Chiswell, C. J. Fox, K. P. Hare, G. A. Lord, H. MacLachlan, M. A. E. Somers, J. N. Wheatley.  
**MEDICINE.**—E. E. E. Attale, A. Cawadias, J. H. Cooper, J. B. Couche, J. Crawford, C. J. Fox, K. P. Hare, \*M. S. Mahmud, W. R. H. Pooler.  
**FORENSIC MEDICINE.**—E. E. E. Attale, A. Campbell, A. Cawadias, K. P. Hare.  
**MIDWIFERY.**—E. E. E. Attale, E. N. C. Annis, A. Cawadias, H. S. Chadwick, R. S. Chambers, K. P. Hare, G. A. Lord, Y. Nadan Lal, H. J. Powell, J. N. Wheatley.

#### \* Section II.

The diploma of the Society has been granted to Messrs. E. E. E. Attale, A. Cawadias, H. S. Chadwick, and K. P. Hare.

## Medical News.

THE annual dinner of the past and present students of St. Mary's Hospital Medical School will take place at the Connaught Rooms, Great Queen Street, W.C., on Monday, October 1st, 1923, at 7 for 7.30. Mr. V. Warren Low, C.B., F.R.C.S., will be in the chair. The honorary secretary is Dr. Hope Gosse.

THE Governors of St. Bartholomew's Hospital have appointed Sir Robert Armstrong-Jones, C.B.E., M.D., to be consulting physician to the department of psychological medicine.

A SERIES of lectures and demonstrations will be delivered at the Royal Sanitary Institute during the coming autumn. A course for sanitary officers will commence on Tuesday, September 25th, comprising the subjects scheduled for the examination of the Institute and the Sanitary Inspectors' Examination Board; inspections and demonstrations have been arranged in connexion with this course, including visits to public and private works illustrative of sanitary practice and administration, with demonstration of the routine of an inspector's office work and duties. A course for meat and food inspectors begins on October 5th; the course consists of

The value of diathermy has been emphasized by both Mr. Walker and Dr. Watson; I had the privilege yesterday of hearing Dr. Cumberland and Dr. Robinson's excellent papers on their work at St. Bartholomew's Hospital. I was more impressed with the results in mild cases of acute epididymitis than in those of chronic prostatitis and vesiculitis. The results in urethritis of the male were, therefore, admitted, disappointing. What is difficult for me to recognize is Dr. Cumberland's statement that diathermy in the prostate is a mild sedative and does not irritate, with its reputed action in what is essentially a chronic fibrotic condition. There must be, as Dr. Robinson suggests, more than the production of deep-seated heating, and it may be the frequency of the oscillations or it may be the action of the heat on the cellular elements. The important points, I gathered from Professor Russ, were: (1) the strength of the current, (2) the time applied, and (3) the current density, and probably the interaction of all three. It is no doubt a possible and very helpful adjunct to the treatment of chronic lesions of the posterior urethra, but after discussing it with Dr. Robinson I must say candidly that I am not yet convinced that it will supplant other more simple and time-honoured methods, such as careful digital massage in combination with specific vaccine therapy, which relieves and clears up the great majority of cases.

Mr. A. CARMICHAEL (Portsmouth) said: I would like to express my appreciation of the papers read by Mr. Kenneth Walker and Dr. David Watson. We have been given much food for thought and much help in treating such obstinate conditions as chronic prostatitis and vesiculitis. To a large number of our medical brethren these two terms are more names, and their connection with metastatic lesions such as arthritis, muscular rheumatism, and attacks the gonococcus through the blood stream similar in action to arsenobenzol, at present we have no means in our possession which will cut short an attack of gonorrhoea by a single day. We still have to rely on the natural forces of the body to overcome the infection, and we can only aid them by local treatment. At the same time, we have to apply what remedies we possess in a careful and judicious manner in order not to aggravate the disease and produce the complications we are dealing with to-day. It is well known to all of us that too strong and too violent irrigations frequently have the effect of increasing the severity of the attack. Too early and too vigorous massage may bring on epididymitis and may produce prostatic and vesicular abscess. I have laid down the following rules in treating acute gonorrhoea: 1. Never to force irrigation on unwilling or nervous patients. The urethra in them may be so sensitive that the introduction of a foreign body—which after all every fluid is—may set up severe irritation and congestion of the prostate and urethra, favouring an extension of the inflammatory process. 2. Never to attempt posterior irrigation for the first week and not to irrigate at all whilst the attack is in a very acute stage with oedema of the penis or blood-stained discharge. At the clinic, where the patients carry out their own irrigation, they can be trusted generally not to do anything that will cause them pain or discomfort, and I think these should be regarded as certain signs of intolerance. 3. Never to massage the prostate and vesicles for prostatitis or vesiculitis; the patient does not irrigate until the acute stage has subsided.

Mr. Kenneth Walker's paper is replete with important histological, anatomical, and pathological information, and stimulating in the many suggestions it offers for new lines of therapy. Lymph spread of infection is, I agree with him, more common than is generally accepted. The anatomical relationship is an important one, and vesiculitis is often undiagnosed; but as the treatment of prostatitis is on the same lines, and as in quite 75 per cent. of cases both tissues are affected, accurate diagnosis is not an absolute necessity. For accurate diagnosis the knee-elbow position is essential during rectal examination, and during massage and manual palpation it is of great assistance. Prostatic and vesicular massage is almost the most important and certainly the least practised method of therapy among the general body of practitioners. In a chronic case with resistant fibrosis the cellular infiltration in and around the prostate lessens the normal and fairly good blood supply, and massage certainly improves this by causing absorption of the deposit. In addition to the three objects mentioned by Mr. Walker, it also improves the general circulation by introducing into the general circulation a better supply of the internal secretion of the prostate. I cannot subscribe to his theory of faradic stimulation of the muscle fibres of the prostate and periprostatic tissues being nearly so efficient as digital massage, which not only acts mechanically but in addition stimulates any striped muscle fibre present. I should like to ask Mr. Walker if he considers the index of efficiency of any method of massage to be the amount of secretion appearing at the meatus subsequently. I do not think the dependence more on the position of the patient and on the technique of the operator? There is the added objection to the electric massager that it is not within the reach of the average general practitioner. It is of interest to find Mr. Walker in one paragraph having new and rather alarming-looking electrode made for him for the therapeutic purposes, in the next faintly damping the Great Metallic Age. Overstimulation, especially in posterior urethritis, is no doubt bad, but in diagnosis and in the observation of the effect of treatment the urethroscope is invaluable in the lower genital tract, and in the treatment of the anterior urethra the expanding and flushing anterior Kolliumman is a great advance on solid instruments and much more scientific in its method of action. I agree with him, however, that bacteriological methods combined with biochemical hold out a greater hope of finally in treatment and in permanent cure. I referred to the value of sulfarsol in acute vesiculitis; in chronic cases I have tried this drug, but not with great success. Non-specific serums and aolan have not been any more successful in my hands. Judged by mouth and intravenous injections of colosal today in combination with prostatic massage are highly and in conjunction with vaccine therapy will clear up most cases. In chronic vesiculitis and prostatitis mixed infection is so often present that an autogenous vaccine is very helpful, and it possible in a chronic case I combine a polyvalent decontaminated autogenous vaccine with the autogenous prepared from the prostatic and vesicular contents. The vaccine should, as Mr. Walker

in suppository antifebrin gr. iv in the place of morphine, to relieve pain; in the subacute and chronic cases I combine with it ichthol m.v. to aid in resolution of the perivesiculitis and prostatitis. In some hyperacute cases, for example, with retention or extreme frequency I have found protein therapy of great assistance in giving rapid relief, and have a preference for sulfarsol, 18 to 24 gr., repeated if necessary in forty-eight hours. The method of artificially reversed peristalsis which he suggests I have tried in two cases and have no doubt that in both the condition was made worse. Like Dr. Watson, I am of opinion that for cases call for either vesicectomy or vesiculectomy. In some of the cases which I have seen, in which the latter operation had been performed, the results were not good, and there are few cases that will not clear up with more conservative methods of treatment. Vesotomy or vasopuncture is a much simpler procedure, and in cases which fail with other methods it is often helpful, if only from the protein reaction to the collagen or other chemical injected. The best operation for vasostomy is Clinton Smith's modification of Belfield's operation.

Mr. Kenneth Walker's paper is replete with important histological, anatomical, and pathological information, and stimulating in the many suggestions it offers for new lines of therapy. Lymph spread of infection is, I agree with him, more common than is generally accepted. The anatomical relationship is an important one, and vesiculitis is often undiagnosed; but as the treatment of prostatitis is on the same lines, and as in quite 75 per cent. of cases both tissues are affected, accurate diagnosis is not an absolute necessity. For accurate diagnosis the knee-elbow position is essential during rectal examination, and during massage and manual palpation it is of great assistance. Prostatic and vesicular massage is almost the most important and certainly the least practised method of therapy among the general body of practitioners. In a chronic case with resistant fibrosis the cellular infiltration in and around the prostate lessens the normal and fairly good blood supply, and massage certainly improves this by causing absorption of the deposit. In addition to the three objects mentioned by Mr. Walker, it also improves the general circulation by introducing into the general circulation a better supply of the internal secretion of the prostate. I cannot subscribe to his theory of faradic stimulation of the muscle fibres of the prostate and periprostatic tissues being nearly so efficient as digital massage, which not only acts mechanically but in addition stimulates any striped muscle fibre present. I should like to ask Mr. Walker if he considers the index of efficiency of any method of massage to be the amount of secretion appearing at the meatus subsequently. I do not think the dependence more on the position of the patient and on the technique of the operator? There is the added objection to the electric massager that it is not within the reach of the average general practitioner. It is of interest to find Mr. Walker in one paragraph having new and rather alarming-looking electrode made for him for the therapeutic purposes, in the next faintly damping the Great Metallic Age. Overstimulation, especially in posterior urethritis, is no doubt bad, but in diagnosis and in the observation of the effect of treatment the urethroscope is invaluable in the lower genital tract, and in the treatment of the anterior urethra the expanding and flushing anterior Kolliumman is a great advance on solid instruments and much more scientific in its method of action. I agree with him, however, that bacteriological methods combined with biochemical hold out a greater hope of finally in treatment and in permanent cure. #### Clinical Studies on Insulin.

N. G. RUSSELL, B. D. BOWEN, and G. W. PUCHER (*Buffalo General Hospital Bulletin* (U.S.A.), April, 1923, p. 41) record their results in the insulin treatment of severe cases of diabetes mellitus. The preparation used was "Iletin"—the name given to the insulin manufactured by Messrs. Lilly, by agreement with the University of Toronto Insulin Committee. The results in six cases of severe diabetes are recorded in detail. They show the power of insulin in checking temporarily the glycosuria. Their results are in accord with those of other investigators, showing that we now possess another means of managing diabetic cases, in addition to the restriction of diet, especially in the severe stages of the disease, where dietary treatment alone is unsatisfactory and often without avail. The sugar tolerance was quite definitely increased in one case, and slightly increased in a second case; but the authors think that if these patients had received dietary treatment prior to the administration of Iletin an increase in tolerance might not have been effected. In their small series of cases the glucose-Iletin ratio appeared quite constant—2 to 3 grams of glucose equalled 1 unit of Iletin. No bad results of the Iletin treatment were noted; but the authors point out that the Iletin was apparently carefully standardized, the cases treated were all severe, and care was taken to keep the blood sugar well above normal. The majority of their patients injected the Iletin themselves. Four cases of diabetic coma are recorded in which insulin treatment was tried. Only in one case could the treatment be carried out fairly promptly, and in this case the patient was twice restored to consciousness from deep coma by the use of Iletin; but unfortunately the patient died of intercurrent pneumonia. In two other cases of diabetic coma temporary improvement followed, but both ended fatally. In a fourth case the Iletin was given very late; no improvement followed, and the case ended fatally. Two charts of blood sugar in a case of diabetes are given showing the striking effect of Iletin upon the utilization of glucose given by mouth.

## Surgery.

#### 169. Rupture of the Intestine without Immediate Symptoms.

A. FLACH (*Schweiz. med. Woch.*, July 12th, 1923, p. 673) records the case of a man who was upset from a bobsleigh, and who cut his face somewhat. He got up at once and walked without help to hospital to have his cuts attended to. They were sutured under local anaesthesia, and a nurse was instructed to give him morphine if the pain of the cuts became excessive after the effects of the local anaesthetic had worn off. When the author saw the patient two hours after attending to his wounds he was informed that the nurse had given him morphine. He had vomited blood ten minutes later, but as he had fractured the septum of his nose it was thought that the blood might come from the nose. The temperature was only 35.8° C. and the pulse of 72 was strong. The abdomen was somewhat retracted and painful, but not very hard, and there was no definite dullness; the liver dullness was normal. The patient could not pass urine, and a catheter specimen was clear. While waiting for a consulting surgeon the patient had severe abdominal pain, for which an injection of pantopon was given. He vomited ten minutes later. By now the temperature in the rectum had risen to 100.2° F., and there was slight dullness in the left iliac fossa. It was agreed in consultation that an exploratory laparotomy was indicated, but the patient no longer felt any pain, and when he got on the operation table he enforced his protests against an operation by drumming vigorously with both fists on his abdomen. The operation was, however, performed, and a 20 cm. rent was found in the jejunum. Resection of the gut was followed by complete recovery.

#### 170. Resuscitation by Intracardiac Injection of Adrenaline.

P. B. CHAMPLIN (*Journ. Amer. Med. Assoc.*, July 21st, 1923, p. 202) reports a case of resuscitation by the injection of adrenaline chloride directly into the heart. Following caudal injection of 0.5 per cent. novocain, preliminary to performing the second stage of a suprapubic prostatectomy, the patient stopped breathing. Unsuccessful attempts were made at resuscitation by the aid of artificial respiration, oxygen, camphorated oil, and atropine sulphate. The radial pulse was imperceptible, and no cardiac sounds could be elicited

over the precordium. The patient's arms were slightly spastic and the pupils were contracted. A 10 c.cm. syringe, with a long spinal puncture needle, was procured, and an injection of 10 c.cm. of a 1 in 1,000 adrenaline chloride solution was given directly into the left ventricle of the heart through a puncture about 5 cm. to the left of the sternal margin, in the fifth intercostal space. This was done about five minutes after the patient had collapsed. The result was almost instantaneous. The heart began beating so vigorously that the pulsation of the abdominal aorta was seen through the abdominal wall within thirty seconds of the injection. There was a strong rapid radial pulse and, at first, feeble respirations, which later became full and strong. The blood pressure, taken about five minutes after the injection, was 200 systolic and 110 diastolic, the same as on entrance to the hospital, but the systolic pressure was 40 mm. higher than it was just preceding the operation. The patient showed no ill effects, except for a single instantaneous sharp shooting pain over the precordium late in the following day. The operation was completed about a week later, under caudal anaesthesia. The prostate was found to have a malignant growth, which on x-ray examination showed metastases in the lungs. The patient was discharged twenty-five days after the second operation with symptoms of lung metastases, but able to be up and about.

171.

#### Gastro-colic Fistula.

G. P. PRATT (*Annals of Surgery*, April, 1923, p. 433), in considering the etiology of these fistulae, classifies the causes in the following order of frequency: cancer, ulcer, following gastro-enterostomy, abscess, and tuberculosis. When due to cancer the primary lesions are more common in the stomach than the colon; generally the viscera are united on a fairly large surface. In other cases there is an intermediate cavity surrounded by adhesions through which the stomach and colon communicate. When due to cancer it is between the transverse colon and pyloric end of the stomach, as a rule. Abdominal pain, discomfort and distension, offensive eructations, faecal vomit, and the similarity of the vomitus and the stools should arouse suspicion of a gastro-colic fistula. Confirmation can be made by the following procedures: Loss of fluid by gastric lavage, as may be seen in hour-glass stomach, recovery of faecal material by lavage, recovery from the stomach of material administered as an enema. Barium meal with x-ray examination and a barium enema are useful aids in diagnosis. On account of the symptoms and digestive disturbance with its inevitable fatal issue laparotomy is indicated, but when carcinoma is the etiological factor little can be done. The gastro-colic fistula following gastro-enterostomy due to ulcer or peritoneal infection offers a better prognosis. There is always the possibility that the causative condition may be removed and the opening successfully closed.

172.

#### Treatment of Pyuria in Childhood.

E. FAERBER and D. LATZKY (*Deut. med. Woch.*, June 23rd, 1923, p. 847) comment on the confusion which still exists as to the etiology and the best treatment of pyuria in childhood. The pus probably comes in most of these cases from the kidneys rather than the bladder, and only in 2 out of 8 cases coming to necropsy did the authors find extensive changes in the lining of the bladder. Cystoscopic examination of 20 children suffering from pyuria invariably showed cloudy, purulent germ-laden urine escaping from the ureters, and only in 2 of these 20 cases was the bladder appreciably affected. Of late years there has been a growing tendency to associate pyuria with general infections such as influenza, measles, and scarlatina, and localized infections such as nasopharyngitis, and in about half the authors' cases some such general or local infection preceded the outbreak of pyuria, the interval between the two being so short that there could be little doubt as to their relationship. The treatment of pyuria in childhood is still most unsatisfactory, the more so because the standards by which the effects of treatment are judged are remarkably loose and shifting. Some writers claim cures in cases in which the urine is still infected, while others believe only in cures being complete when the bacteriological as well as the clinical evidence is in their favour. The authors have analysed the results of their treatment of 164 children, classifying them according as they were infants or older children, and according as they were in-patients or out-patients. The out-patients were treated only with salol, urotropine, acids, or alkalis, other treatment being seldom given. The in-patients had a greater variety of treatment, and when salol, urotropine, and other urinary disinfectants proved futile, vaccines, salvarsan, & other remedies were tried. It would be natural to expect the in-patients to show better results than the out-patients; but while only 25 per cent. of the in-patients were cured after six weeks' treatment, 56 per cent. of the out-patients were cured

summation of signs and symptoms which go to make the basis of our prognosis.

After a considerable experience in the use of electro-cardiography as a purely clinical method, some conceptions have seemed to be helpful in conveying to students our ideas as to what exactly is the information we obtain through this galvanometric record.

In the first place, it is to be recognized that we have a galvanometric record which represents the summation of all the fluctuations of electric potential that occur between the sites of application of our electrodes.

If we consider this fluctuation of potential from the point of view of the electronic theory—which theory is fundamental in modern molecular physics, and is the accepted basis of all practical teaching in "wireless"—we may look upon the electro-cardiogram as a record sent merely an electronic pulsation in the body. We also must realize that we can pick up this electronic pulsation by electrodes placed on the body in any such position that the heart influences the circuit between them.

The electro-cardiogram obtained varies in its form according to the position the electrodes occupy relatively to the heart, but in all cases it is to be remembered that the galvanometric record can only be a summation curve of variations of potential which occur during the cardiac cycle.

It may be added that where the electrodes are in a fixed position the electro-cardiogram may be altered by a change of the position of the heart relatively to the electrodes; this, for instance, occurs markedly in the third lead (left arm—left leg) in some people where the heart moves considerably with respiration.

As a result of the work of Sir Thomas Lewis and others this electro-cardiogram has been analysed with most illuminating results. To follow this analysis is difficult for those not well versed in electro-cardiography, but to-day all students who come to the bedside have a working knowledge of the "mechanism of the heart beat" due to the efforts of these investigators.

Thus we know that the starting-point of the heart beat is at the sinus node or "the pace-maker," spreads over the auricle, reaches the auriculo-ventricular junction, and inaugurates there the changes which lead to ventricular contraction. This stimulus for ventricular contraction first traverses the bundle of His, the A-V bundle, which bundle divides into right and left branches to supply the respective ventricles. In dealing with the conduction of the impulse in this A-V bundle system it may be noted that Keith Lucas mentions the work of Mines and Roake, which suggests that the whole system may be analogous to an enormous myoneural junction. As any rate, the ventricular conducting system, as known to-day, consists of four distinct portions—namely:

A. The undivided A-V bundle.  
B. The right and left branches of the bundle.  
C. The enormous arborization formed by the division and redrawing of these branches into an interlacing network of fibres lying beneath the endocardium all over the inner surface of each ventricle.

D. Extending from the arborization, filaments of this conducting tissue pass in amongst the branched fully striated true muscular fibres of the myocardium, to end in relation with the semi-striated Purkinje fibres.

It is necessary to visualize this conducting mechanism, and this may be helped by comparing it to the ignition system in a two-cylinder motor engine, but remembering that the cylinders (that is, right and left ventricular chambers) must be ignited simultaneously. We have two wires, one leading to each cylinder. These represent the A-V bundle branches. When we consider the cylinders, we have, not one point of ignition, but we have innumerable points all over the myocardium which represent, as it were, the sparking plugs. In order that these sparking plugs may be ignited simultaneously we have the tremendous arborization formed by branching of the A-V bundle. The advantages of this enormous anastomosis are obvious. It implies once it has got past the larger branches of the bundle, and also that if there is a block in the anastomosis at any point it will need to be of very considerable magnitude to have any effect upon the igniting stimulus.

The cardiac mortality attending aberration of the Q.R.S. complex in all derivations of the electro-cardiogram practically follows that of the control series.

The cardiac mortality attending aberration of the Q.R.S. complex in all derivations of the electro-cardiogram practically follows that of the control series.

To follow up the analogy, and by means of it to interpret what Lewis and others have shown us experimentally, we have to form the conception that once an impulse reaches the arborization it will spread all over the myocardium in what we recognize as a relatively short period of time. We also have to realize that if the impulse arrives or starts in one cylinder or the arborization into the other cylinder or ventricle, it will spread almost simultaneously through the arborization, to explain why the heart will contract, apparently normally, so far as all our clinical findings go, after there has been a lesion which completely destroys one of the branches of the A-V bundle. It was by accurate and scientific tracing of the spread of the electrical excitation over the living ventricle that these investigators have shown us how the stimulus spreads, and how an electro-cardiogram can be made to alter as the result of the injury of one or other branch of the A-V bundle. It seems to-day that the electro-cardiogram has placed us in such a position that we are able to localize a lesion which occurs in the ventricular conducting system of the heart. The recognition of a complete heart-block—that is, a lesion in the undivided A-V bundle, where the auricular impulse fails to pass to the ventricle, and the ventricle beats at its idiosyncratic rate—is a simple matter when an electro-cardiogram is available. The certainty of the presence of a complete, incomplete, or partial heart-block is, of course, a very great factor in forming a prognosis.

FIG. 1.—Diagram of normal electro-cardiogram.

Without going into a very detailed consideration of the electro-cardiogram, it may be sufficient to say that in the diagram above (Fig. 1) the Q.R.S. group of deflections are taken to represent the summation of the changes which follow the flow of the impulse along the right and left branches of the A-V bundle. How much of this electric change is due to the spread in an arborization of the branch we do not think can be taken as settled. There is no doubt, however, that amongst those using the electro-cardiograph it has become recognized that certain changes in the electro-cardiogram indicate a lesion, either temporary or permanent, in the right branch of the bundle, and an opposite variation indicates a lesion in the left branch. Figs. 2 and 3 show the electro-cardiograms in such a lesion.

From a practical point of view in clinical medicine the importance of these electro-cardiographic records lies in the fact that, taken statically, they indicate a very grave prognosis, and it must be borne in mind that there is no other means at present except the electro-cardiogram of diagnosing such a lesion.

Dr. Williams, of the Mayo Clinic, recently published a most important set of statistics bearing upon the value of the electro-cardiogram from a prognostic point of view. Taking his figures in connection with this physical sign of a bundle-branch lesion or arborization block lesion, he gives the following summary of 112 cases:

"The cardiac mortality attending aberration of the Q.R.S. complex in all derivations of the electro-cardiogram practically follows that of the control series."

a somewhat lessened malignancy. Other points of clinical interest which emerge from the analysis are that no fewer than one-third of patients seen within six months of the first symptom being noticed by them already showed (the spinal cell group being excepted) extension of the new growth to the broad ligament, and that fewer than 10 per cent. of such patients lived more than one year after operation. In almost one-half of cases in which the entire length of the cervix was affected by cancer, secondary involvement of the corpus uteri was noted. In 97 per cent. of the patients the first symptom noted was some unusual form of vaginal discharge (bleeding or leucorrhoea); and the first symptom in 87 per cent. consisted in some form of vaginal haemorrhage. The study affords no confirmation for the view (which has been advanced from comparison with cancer of the breast) that it is harmful to perform diagnostic curetting some days before radical operation.

#### 179. Myomectomy during Pregnancy.

A CASE recorded by FRUHHOLZ and HAMANT (*Bull. Soc. d'Obstét. et de Gynécol. de Paris*, 1923, 4, p. 311) shows how tolerant the pregnant uterus may be of myomectomy. The myoma, which was the size of the foetal head, arose in the anterior portion of the cervix, had caused dilatation of the os externum to more than 1 inch in diameter, and had displaced backwards and elongated the cervical canal. The patient's general condition had been reduced by continued metrorrhagia during the fifth and sixth months of pregnancy; symptoms of vesical or rectal compression were absent. The myoma was enucleated per vaginam at the beginning of the seventh month; it weighed 250 grams. The patient was delivered spontaneously at term of a healthy infant. The opposite side of the picture is seen in a case described (*Ibid.*, p. 306) by PLANCHU and GAUDON: during the seventh month of pregnancy a primipara aged 30 was found to have a pediculated subserous myoma inserted near the left tube. Thirty-six hours after ablation of the myoma during the eighth month the patient was prematurely delivered of a infant weighing 2,350 grams.

### Pathology.

#### 180. Serology in Brain Tumours.

F. P. MOERSCH (*Journ. of Nervous and Mental Disease*, July, 1923, p. 16) gives statistics of and observations on a series of cerebral tumours. He notes the absence of any uniform serological criteria and, at the outset, emphasizes the need for combined pathological and clinical investigation if the former is to be estimated at its true value. He finds that the type of tumour does not appear to exercise a definite influence on the serological characteristics of the cerebro-spinal fluid, and though the invading forms such as glioma give the more unusual results, this is not so much from their nature as in virtue of extension to the membranes. Locality seems unrelated to serology, but invasion of the membranes or ventricles may be factors in the production of a high cell count. The influence exerted by inflammatory conditions on the cell count does not appear to warrant special attention. The author considers that a high cell count, while contraindicating, should not altogether exclude a diagnosis of tumour of the brain. The latter is to be differentiated from inflammatory conditions, vascular disease, multiple sclerosis, and migraine, most of which should cause little confusion, but in the more acute types with cranial nerve involvement the symptoms simulate those of cerebral tumour, and similarity in the serological findings may create further doubt. Acute abscess gives the general signs and serological reactions of a meningitis. This rule, however, does not always obtain, and in blood-borne abscesses or in those originating in otitis media the findings are occasionally negative. Chronic abscess may produce results varying from the normal to a polymorph or lymphocyte reaction, and the author considers it inadvisable to make a diagnosis of abscess unless the focus of infection can be determined. He notes that a positive Wassermann reaction on the spinal fluid in cases of brain tumour is not unknown, but advocates careful investigation before submitting a patient to antispecific treatment. On the contrary, a negative finding should not cause the possibility of concurrent syphilis to be overlooked.

#### 181. The Histology of the Cure of Uterine Epithelioma.

THE changes produced by irradiation—chiefly, but not exclusively, radium—on cancer cells of uterine baso-cellular epithelioma are detailed by Professor Dr. FRANS DAELS (*Arch. of Radiol. and Electrother.*, June, 1923, p. 1). They commence after a latent period of ten to fifteen days, and are not met with in cases of spontaneous degeneration. The action first affects the nucleus, causing either an actual rupture or a destruction, sometimes with eosinophilia or megakaryocytic

degeneration in consequence of nuclear fusions from loss of karyokinetic power. Rapid and extensive karyorrhexis of the cancer cells occurs without any participation by blood cells or degeneration of the normal tissues. A phenomenon characteristic of irradiation results: it is a progressive necrosis caused by pyknosis or achromatosis accompanied by eosinophilia or vacuolization of the protoplasm and phagocytosis by polynuclear blood cells, and it results in the destruction of a large number of alveoli. The cancer cells become transformed into giant cells and giant nuclei, the effect of which may be necrosis with polymorph leucocyte invasion or atrophy with fatty degeneration and without leucocyte infiltration. The author admits that polymorph leucocytes occur only in association with spontaneous degeneration or in irradiation transformations as a result of concomitant infection or the necrosis of cancer cells, and play no active part in the regression process, in which connective tissue is likewise inactive. On the other hand, infiltration of lymphocytes would appear to be essential to effective reaction against cancerous proliferation. The detection of giant cells of a non-malignant type and of normal follicles as a result of irradiation led the author to adopt the hypothesis of the liberation of substance to which the tissues react by lymphocytic infiltration and giant cell formation, and he draws attention to the close resemblance in this connexion with the histological picture found upon the healing of the follicles arising after experimental injection of killed Koch bacilli.

#### 182. Hepato-nephritis.

CHAUFFARD (*Arch. de méd., cir. y esp.*, June 23rd, 1923, p. 524) states that this term was introduced by Richiardi to designate certain forms of severe icterus. Although it is applied to a simultaneous inflammation of the liver and kidneys, certain conditions must be fulfilled. In the first place, the hepatic and renal lesions must be the predominant feature in the clinical picture, so that the simultaneous involvement of the liver and kidneys which occurs in acute infections such as typhoid fever or pneumonia is not an example of hepato-nephritis. Secondly, the lesions of the liver and kidneys must be due to the same cause. Thirdly, the hepatic and renal lesions must be definitely synchronous. Under these conditions hepato-nephritis occurs in only a small number of diseases. Two of them—namely, spirochaetosis ictero-haemorrhagica and syphilis—occur in our climate; another two—namely, yellow fever and bilious haemoglobinuric fever—are tropical diseases; and the fifth—hepato-renal amyloid disease—is a condition very rarely met with nowadays, due to chronic suppuration or syphilis.

#### 183. Variations of the Blood Count due to Mechanical or Nervous Causes.

J. TINEI (*Arch. Mal. du Cœur, des Vaisseaux et du Sang*, July, 1923, p. 521) remarks that the results of blood counts are not only falsified by various errors of technique; they may be disturbed equally by many physiological factors which may greatly modify the blood formula. It has been shown that the blood formula obtained by pricking a finger never corresponds, except relatively, to the actual composition of the blood. Remarkable variations are observed when blood is collected from the finger, the lobule of the ear, from a vein, from the heart or other internal organs. Actually one never finds any variation at all resembling that of the venous blood and of the heart blood, where occasionally the numbers may be reversed. Widal, Bezançon, and Labbé describe this as the "leucocyte exodus." Chiray (1906) found that after injections of egg albumen in a rabbit there was a considerable excess of cells in the peripheral blood without alteration of that of the heart. The same rapid "hyperglobulia" of the peripheral circulation occurs in aeronauts. The author has found that the leucocyte count may be greatly modified by testing the oculo-cardiac reflex for a few seconds. Tinei gives several examples of profound alterations in the leucocyte count occurring during and after compression of the eyeball. Furthermore, vaso-constriction (for example, by a spray of ethyl chloride) produces a relative leucopenia, especially affecting the polynuclears. Vaso-dilatation, on the contrary, is accompanied by immediate hyperleucocytosis, with excess of polynuclears. Raising the hand and allowing it to fall causes a leucocytosis, particularly of polymorphs and large mononuclears, and a similar change is produced by moderate compression of the arm by the brassard of a sphygmomanometer. In hemiplegia there is a marked polymorph leucocytosis in the cold, cyanosed, and paralysed hand. The author concludes that all these facts prove that, beside important errors in technique, capable of falsifying a blood count, there exist numerous physiological causes of error, resulting more particularly from vaso-motor phenomena. These observations show that the peripheral "blood formula" is never more than relatively correct and is susceptible of variation by many influences—mechanical, emotional, and nervous.

# A Concentrated Nutrient

*containing Bone Marrow (12½%),  
Yeast Extract and their associated  
accessory factors (A. & B.), together  
with Hæmoglobin & Malt Extract.*

## Byno'tone

TRADE MARK

is a concentrated nutrient of wide applicability in the treatment of malnutrition in infants, adolescents and adults. It also provides a source of supply of accessory food factors which are necessary for normal metabolism particularly in infancy but also in adult life.

'Bynotone' is in the form of a granular powder and thus presents its various elements in a highly concentrated form. The preparation is not unduly hygroscopic and keeps perfectly if the container is well closed.

*Full particulars and a clinical trial sample sent upon request.*

At the end of the x-ray treatment there was no perceptible thickening, movement was free from pain, and there was a complete range of passive movement although active movement was a few degrees short of full. (See Fig. 2.)

Although this is a recent example it is by no means unique. During 1921 I was engaged in the investigation of the effects produced by the action of x rays on various conditions in which the effects of fibrous tissue formation were responsible for certain symptoms which failed to react to other physiotherapeutic remedies.\* However, grouped there was one outstanding feature in all the cases in this series—namely, the marked softening of excessive fibrous tissue by a comparatively short treatment with hard filtered x rays. Clinical improvement was shown by such evidence as (1) the relief of pain when a nerve was being strangled by cicatricial tissue in cases of superficial scars and in certain cases of neuromas; (2) by greater and more rapidly secured freedom of movement in such a joint as the shoulder after prolonged suppurative and extensive operations in its neighborhood; (3) by a greater range of action in cases of transplanted tendons for injuries of the musculo-spiral nerve; (4) by improvement in peripheral circulation where the brachial vessels were being constricted by scar tissue following gunshot wounds. Even in some cases of Dupuytren's contraction of long standing there was considerable softening of some of the lateral bands although the central

FIG. 1.—Before treatment. FIG. 2.—After treatment.

palmar mass held out and so no clinical improvement resulted. Although the majority of these observations were made on cases of war injury, a sufficient number of cases have been treated in civilian practice to prove that the same treatment is applicable. The action of radiotherapy which is now under consideration has been observed by others beside myself, but it does not appear to be at all widely known.

In post-operative radiotherapy of cases of amputation of the breast the softening effect on the scar tissue left after extensive dissection is so striking that its use for this purpose alone—apart, that is, from any prophylactic effect—would almost be justified.

As another example we may take the action of radiotherapy on keloidal tissue; it was in fact this action that first suggested to me the investigation on fibrous tissue generally. On consulting such references as came readily to hand I discovered that radium treatment on scar tissue had been carried out by Dr. W. Stevenson of Dublin, and that the results had been published by him in two subsequent papers.† It is hardly necessary to point out that the only essential difference between radium therapy and x-ray therapy is in the wave-lengths employed in each case. Since radium is not so generally available as x-ray apparatus this reference to Stevenson's work confirmed me in my

I believe that there is scope for radiotherapy in certain various adhesive bands.

I have been dealing with conditions which are similar inasmuch as we can group them as traumatic in origin. I should like to close by pointing out that the morbid conditions end in a fibrosis which is not always beneficial to the patient. Our nomenclature of disease is too often purely topographical. Attention is directed from the fact that such apparently disconnected affection as chronic arthritis, lumbago, pleurodynia, sciatica, and brachial neuritis, at any rate as regards their later stages are in reality often the manifestations of that inflammation of the connective tissue known as "fibrositis." I matters little for our present purpose what the precise etiology of such cases may be provided that we realize that under the heading of "fibrositis" we are including the cases in which the morbid process is essentially the inflammation of the white connective tissue, be the situation muscular, aponeurotic, synovial, or perineuritic. While medicinal treatment or a masterly inactivity may effect a physical cure, functional restoration can only be obtained by treatment by x rays in certain forms of sciatica and neuralgia may be explained by the softening action on certain adhesive bands.

\*These results were published in the *Archives of Radiology and Electrotherapy* for August, 1921.

†British Medical Journal, July 4th, 1914, and *Lancet*, March 23rd, 1913. *British Medical Journal*, December 2nd, 1913. *Journal of Radiology and Electrotherapy*, May, 1921.

May I, on your behalf, accord a very hearty welcome to Dr. Banting, who has so kindly consented to join in our discussion? As our very distinguished visitor, I will ask him to speak first. If he has anything new to tell us, we shall be very interested to hear it. If he has nothing new, then we shall like to hear the old story again from his own lips. I hope that Dr. Banting will avail himself of some of the time usually allowed to the opener of a discussion, and which, upon this occasion, I have not felt it necessary to utilize.

#### OPENING ADDRESS

BY

F. G. BANTING, M.D.,  
Toronto.

DR. BANTING said that Mr. Best and his associates thanked the medical profession for the way in which it had received the result of their experiments. He outlined the story of the research which led to the preparation of insulin in sufficient quantity. Many attempts were made to prepare extracts of the pancreas to furnish the active principle. Following ligation of the pancreatic ducts, dogs did not become diabetic and the acinous cells of the gland alone degenerated. They had ligatured the ducts and ten weeks later the degenerated pancreas was removed and extracted with saline. In a depancreatized dog the blood sugar rose perhaps 20.40 per cent. in a few days, the wound broke down, a scum formed at the inner canthus of the eye, the animal weakened, developed great hunger and thirst, underwent a rapid loss of flesh and was therefore most suitable for experimental purposes. The injection of the above

tract into such a dog caused a fall in the blood sugar, in strength, and the animal lost its ravenous appetite. This was not a suitable method of preparing insulin. Ongoing continued injection of secretin with a view to stimulating the acinous cells and thereby destroying trypsin was found to be uncertain. An extract was then prepared from the pancreas of foetal calves; up to the fourth month the acinous cells contained no trypsin granules. This extract was found to be very potent in lowering the blood sugar, and the second dog was killed by an overdose, and died with symptoms which are now known to be those of hypoglycaemia. The problem, then, was to extract the internal secretion from the whole pancreas by some chemical means which would destroy the proteolytic ferment and leave the insulin unharmed. Alcohol in certain percentages was tried. Dr. Cobb succeeded in fractionating out the active principle with 82 per cent. alcohol. Since then rapid progress had been made, and the product now contained no protein, was non-irritating, and more easily standardized.

Insulin in proper dosage in the laboratory reduced the blood sugar to normal or less; it rendered the urine sugar-free and by its means a depancreatized dog could be kept alive at least three times as long as without it. Without insulin such a dog would live from eight to twenty days. Dr. Banting with insulin had kept a dog alive for seventy days; the animal was then killed and no islet tissue was found. The liver of a depancreatized dog did not contain more than 0.5 per cent. of glycogen, but after insulin and glucose as much as 18 per cent. of glycogen might be present; insulin therefore enabled the dog to store glycogen in the liver. Fat replaced glycogen in the liver of depancreatized dogs. Four days after the operation the liver might contain 11 to 12 per cent. of fat and no glycogen, whereas four days' treatment with insulin might lead to the disappearance of fat and the appearance of 12 to 15 per cent. of glycogen. Adequate doses of insulin would control all forms of hyperglycaemia. The effects of overdose as seen in a rabbit accompanying the fall in blood sugar were hunger, the animal chewing the woodwork of its cage; it then became dull, had periods of intermittent convulsions and unconsciousness followed by coma. If given glucose the symptoms were relieved or prevented.

The clinical work had been done by Professor Duncan Graham and Drs. Campbell, Gilchrist, and Fletcher. There was no fixed method at present of managing diabetic patients. We were still in the course of experimental work. In Toronto if the case was at all severe it was admitted to hospital for three weeks for training in routine and the

working out of tolerance. During this time a careful history was taken, special stress being laid on the question of heredity or the possibility of infection. The patient was kept for twenty-four hours on his usual diet to judge of the severity of the case. He was then put upon the "basal requirement diet":  $\frac{3}{4}$  gram of protein per kilo body weight was given per diem; a larger allowance of protein was made if the patient was not fully grown. The remaining calories were made up of carbohydrate and fat in the proportion of 1:1.3 (modified Woodyatt diet). The patient was kept on this for three or four days. If a mild case he became sugar-free; if severe, the sugar output became more constant. If sugar-free the carbohydrate was raised. If the patient could take 500 calories over and above the basal requirement insulin was not given.

The output of sugar was of value in estimating the initial dose of insulin. One unit of insulin might be regarded as metabolizing 2 to  $2\frac{1}{2}$  grams of carbohydrate in a severe case, but the exact quantity varied in different cases and in the same case at different times. Where infection was present the amount was also less. In mild cases one unit of insulin might metabolize 5 or 6 grams. The initial dose of insulin should not be sufficient to render the patient sugar-free; there was not sufficient glycogen in the liver to act as a buffer. As a rule 5 units might be given to begin with, unless the patient was comatose. The dose should be given one hour before meals, and never more than once a day. It was given before meals because in a normal individual the presence of carbohydrate in the blood stream stimulated the islet cells of the pancreas. It was advisable to keep the patient sugar-free by dieting and insulin; when sugar-free the pancreas tended to produce insulin. One patient, who was taking a diet of 620 calories, including 20 grams of sugar, passed 15 grams of sugar; but after treatment with insulin he was sugar-free on a diet of 980 calories containing 40 grams of sugar. There was evidence in many cases of an increasing tolerance as the result of insulin treatment, but this was not so marked in those cases who had been adequately controlled by diet. The frequency of blood-sugar estimation necessary to control treatment was still uncertain.

#### DISCUSSION.

Dr. P. J. CAMMIDGE (London) said that for many years the name diabetes mellitus had been generally applied to any condition in which sugar was passed in the urine, but as glycosuria might arise from a variety of causes its significance in that sense was merely symptomatic, like albuminuria or fever. Recently an attempt had been made, particularly by Allen, to restrict the term to glycosuria dependent upon disease of the pancreas, but in the absence of some reliable diagnostic sign by which pancreatic might be distinguished from non-pancreatic cases during life such a classification was merely juggling with words. Fortunately, however, the means were now available, and by appropriate analyses of the blood, urine, faeces, etc., it was possible to determine with considerable certainty whether a deficiency of the internal or external secretion of the pancreas existed in any particular case, and also to recognize or exclude most of the other causes known to give rise to hyperglycaemia.

Time would not permit him to deal with all the various analytical methods by which one form of glycosuria might be differentiated from another, full details of which were given in his book, entitled *New Views on Diabetes Mellitus*, which would shortly be published by the Oxford University Press; he therefore confined his attention to one, the relation of the "hydrolysis and difference values" of the blood to its sugar content before and after a standard breakfast. In this test a specimen of the patient's blood was taken from a finger prick, fasting, and part was used to determine the percentage of sugar by the Folin and Wu process in the ordinary way; the other part, after being freed from protein, was boiled with dilute hydrochloric acid, neutralized, and its reducing power determined by the same process. The figure indicating the latter he termed the "hydrolysis value," while the difference between this and the original value was called the "difference value." After the patient had taken the test breakfast, examination of the blood was

Reviews.

MAX, MAGIC, MYSTICISM, AND MORALS.

IN his *Primitive Mentality*, Professor Lévy-Bruhl of the Sorbonne takes as a working hypothesis his previous work set out in *Les Fonctions Mentales dans les Sociétés Inférieures*, published in 1910. As the translator, Miss Crome, states in the preface to the English version, the earlier book laid special stress upon the law of participation, considered in relation to the principle of identity, and also upon the fact that the primitive has little perception of the law of contradiction. In his new book Professor Lévy-Bruhl aims at showing what causation means to primitives and the inferences to be derived from their idea of it.

In his introductory remarks the author argues that the primitive's distaste for the discursive operations of thought, the restriction of his ideas to a small number of objects, and his lack of reflection, are not due to inherent incapacity or natural inaptitude; to understand the problem properly, we must recognize that the primitive makes no distinction between this world and the other, between what is actually present to sense and what is beyond. He actually dwells with invisible spirits and invisible forces, and to him it is these that are the real and actual. Professor Lévy-Bruhl asks us to abandon the belief that primitive minds are orientated like our own and react as ours do to the impressions made upon them; for, when we find they fail so to do we are apt to explain this failure by such hypotheses as the feebleness and torpidity of their minds, stupidity, perversity, child-like ignorance, etc. This merely leads to denying beforehand the mental activity of primitives as a rudimentary form of our own, and consequently to considering it as puerile and almost pathological.

The primitive's indifference to secondary causes; his fear of mystic and invisible forces, dreams and omens; his practices of divination; his firm faith in the rest of oracles; the mystic among him puts into accident, misfortune, and the causes of success; the equally mystic meaning of the white man's appearance and of the things he brings with him; his dislike of the unknown and his reluctance to abandon old customs in favour of new through fear of giving offence to ancestors and spirits by too ready acceptance of change, with his consequent attitude to European remedies—are all dealt with in a highly attractive manner throughout the fourteen chapters of a most erudite book.

In interesting chapters discussing the subject of omens the author deals, amongst many other things, with the primitive's fear of facts or events which are unusual, or of individuals who are more or less teratological, like the *monstrous and portentous* of the Romans. When an omen of this kind appears the universal plan is to cancel it as quickly as possible: to guard against that which the monster portends it must be made to vanish. Abnormal presentations are dealt with by the primitives as a dangerous portent—for example, in foetaling births the child is slain, while if a goat is giving birth to a kid and the head appears first the animal is slaughtered. Where a woman, in labour for the first time, gives birth to twins an old woman of the village amongst the Kikuyu of East Africa, generally the midwife, stuffs grass into their mouths until they are suffocated, and then throws them out into the bush. If a cow or a goat bears twins the first time, the same practice is observed. In British East Africa, if a child is born feet foremost it is smothered. The reasons given are that if the infant is permitted to live their crops will all wither up from drought, their cattle will die, and many other evils befall them. Especial fear is shown of children who cut their upper teeth first, as they prevent the rain from falling. To counteract this, such children are buried alive in wet ground. It is interesting to note the survival of a feeling of "uncanniness" about 'Primitive Mentality'. By Lucien Lévy-Bruhl, Professor at the Sorbonne. Translated by Lillian A. Crome. London: George Allen and Unwin, Ltd. 1922. (Demy 8vo, pp. 452, 16s. net.)

such an event in Scotland, although there the belief is attenuated and the risk falls on the child itself: "They that cut their teeth abune, Will never wear their marriage shoon."

DISSEMINATED SCLEROSIS.

The American Association for Research in Nervous and Mental Diseases has published a report of the papers and discussions at its meeting at New York on December 27th and 28th, 1921, on the subject of *Multiplic Sclerosis*, which is on the same general lines as the report issued in 1921 on acute epidemic encephalitis (lethargic encephalitis). In the present volume there are four sections, dealing with general and historical considerations, general and special symptomatology, the differential diagnosis, course, and treatment, and the pathogenesis of disseminated sclerosis, to which twenty-six medical men have contributed. Dr. W. Timmes's historical retrospect is illustrated by the frontispiece showing Sir Robert Carswell's drawing of the spinal cord, which appeared in his work on *Pathological Anatomy* (1838). In America the distribution of the disease resembles that of simple glioma being high in the region of the great lakes, and Dr. C. B. Davenport, who deals with its geographical and racial incidence, suggests that the Scandinavian race is especially subject to it, and that the hereditary factor, whatever may be found to be the exciting cause, may play a part in its development. The commission does not share the view that the disease is so infrequent in America as some authorities have stated. A plea is put forward by Dr. C. L. Dana for the prolonged application to the etiologic problems of this disease of the methods of ecology, or the science of the relation of a living organism to its environment, which was originally linked up with botany but is now applied to animal life.

According to Dr. B. Sachs, the differential diagnosis is made by means of very small test objects as many as sixteen of them arise. Reference is made to Klingman's detection of minute multiple absolute scotomas in or near the point of fixation and rather more numerous in the temporal than in the nasal portion of the field of vision, in patients in whom other examinations might have only noted a large diffuse relative scotoma. The commission did not find any evidence of implication of the sympathetic system or of the endocrine glands, and ascribes its immunity to the automatic action the segmental mechanism of the spinal cord is able to assume in relation to the visceral functions when cut off from higher influences. The difficult question whether the morbid process is primarily degenerative or an acute inflammatory commencement and later changes of a purely degenerative nature, the other which never presents any evidence of inflammation, and the process is degenerative from start to finish. Search for a causal spirochete or other organisms gave negative results, and the Wassermann reaction of the cerebro-spinal fluid was uniformly negative, but a parietic type of colloidal fluid was uniformly positive.

'Multiple Sclerosis (Dissiminated Sclerosis). Association for Research in Nervous and Mental Diseases—A Series of Investigations and Reports. Vol. II (1922). New York: Paul P. Hoeber, 1922. (Demy 8vo, pp. xvi+211, 1 plate, 22 figures, 5/3s. net.)

five cases of diabetes with insulin, and allowing for a large measure of enthusiasm it had appeared to produce almost magical effects. Dr. Banting seemed to have already answered one of his questions: Was a patient any better off for being sugar-free if the blood sugar remained considerably above normal? Such a patient might be metabolizing more carbohydrate and gaining in weight and well-being, but with hyperglycaemia was he safe? Possibly if it had been ascertained that glycosuria occurred with a low blood-sugar threshold, they could make use of a trace of glycosuria as the guide to insulin dosage. Dr. Banting had advocated Woodyatt's "basal requirement diet." Dr. Nixon had found that a most practical standard diet. It enabled them to adjust the insulin dosage to a diet which was adequate. Moreover, Woodyatt's formula for calculating the proportion of fat to carbohydrate and protein had proved most useful. As an example, a woman with glycosuria on whom the surgeon wished to perform myomectomy was rendered sugar-free in the urine by diet, but had a high degree of acetonuria. The diet was recalculated, so that the fat was equivalent to twice the carbohydrate plus half the protein. In three days she was acetone-free and the operation was successfully performed. He had had an example of the personal factor in tolerance of insulin. A man, aged 29, was rendered sugar-free (in the urine) by complete starvation, but he developed glycosuria on a diet containing only 300 calories. He was given 5 units of insulin during starvation and he was not given a meal until one

and a half hours later. Before this meal his blood sugar was again estimated. His fasting blood sugar was 0.3 per cent. One and a half hours after insulin, while still starving, his blood sugar was 0.29 per cent. This man was ultimately enabled to take a diet containing 1,679 calories with a daily dosage of 40 units of insulin injected as 20 units twice a day.

The symptoms due to over-dosage of insulin were difficult to determine. A man of 40 receiving 20 units of insulin

Blood sugar after 50 grams of glucose by mouth.

daily for three days developed sudden partial aphasia; he was given glucose before his blood sugar could be estimated. By the next day his aphasia had practically recovered; but this patient had previously shown symptoms of angina pectoris. This case rather frightened him, but he was not convinced that his aphasia was due to insulin. Another man, aged 35, receiving 20 units of insulin daily, told him that since the injections his feet suddenly become swollen at night and he felt tinglings in his legs; but this patient's blood did not show hypoglycaemia. A girl, aged 14, presented an example of the difficulty occasionally experienced in deciding whether a patient was a true diabetic. Five weeks before she came under observation she complained of thirst, polyuria, weakness, wasting, and glycosuria. She was put on a diet before her blood sugar was estimated. The glycosuria disappeared and her blood sugar was no more than 0.13 per cent. In hospital her blood sugar fell to 0.8 and 0.75 per cent., although she was supposed to be taking 7 ounces of bread a day. She had also ketonuria. She was tested with 50 grams of glucose, given by mouth, and her blood-sugar curve was characteristic of true diabetes. Then she admitted that she had been afraid to eat the bread permitted in her diet. Ultimately she was found able to take a diet containing 3,000 calories; her blood sugar remained about 0.1 per cent., and she had been sent home as not needing insulin treatment. She was a potential diabetic with a high sugar tolerance. An excessive indulgence in chocolate had produced her first symptoms of diabetes.

Dr. J. K. RENNIE (Glasgow) said that the treatment of diabetes had undergone so marked a change during the past few years that a consideration of the results obtained under the various methods of treatment was not without interest. The following figures were obtained from the records of admissions to Dr. Cowan's wards in the Glasgow

Royal Infirmary, and covered a period of thirteen years. For convenience he had divided the cases into (1) old, (2) Allen, (3) insulin, the terms applying to the type of treatment adopted in each group. So far as possible only cases of undoubted diabetes had been included, but as all the "old" and a few of the "Allen" cases were under treatment before the routine use of blood sugar and glucose tests the records in these groups were necessarily less trustworthy. Needless to say, information had been received from time to time of the subsequent death of many of these patients, but as much of that information was unreliable it had been disregarded. Only cases which died in hospital were included in the following table:

|                | Patients Treated. | Improved. | Stationary or Worse. | Died. | Mortality. |
|----------------|-------------------|-----------|----------------------|-------|------------|
| 1. Old ...     | 49                | 29        | 13                   | 8     | 16.3%      |
| 2. Allen...    | 47                | 39        | 6                    | 2     | 4.2%       |
| 3. Insulin ... | 10                | 10        |                      |       |            |

1. "Old" Cases.—This group included all cases treated under the various dietetic régimes in vogue before the introduction of the well known starvation methods of Allen and of Graham. A reference to the ages of the "improved" group showed that 11 cases were under 35 years of age, while in the stationary group 9 of the 12 cases were under that age, and 3 of these under 20. Of the deaths all 8 occurred in coma; 7 of these patients were under 35, 4 under 20.

2. "Allen" Cases.—Forty-seven cases were treated on "Allen" lines, and an improvement, more or less marked, occurred in 39. In this group, however, the average age was rather less than in the corresponding group of "old" cases, 17 being under 35 years. Of the 6 cases in the stationary group 3 became dissatisfied with restricted diet and left hospital irregularly, a happening which was becoming increasingly less common—probably the only good result of the publicity which the treatment of this condition had received of late in the public press. One case had a progressive pulmonary tuberculosis on admission and went to a sanatorium; and one, a girl of 17, suffered from mitral disease with failing compensation. The sixth case, an elderly man with long-standing diabetes and gangrene of the toes, made no progress under treatment. Of the two patients who died, one was admitted with air hunger, and died in coma in thirty-six hours. The second case was that of a youth of 17 in whom symptoms had first manifested themselves five weeks prior to admission. He was poorly nourished, but bright and alert, and nothing abnormal was found on physical examination. The urine contained sugar in amount, acetone was present, but there was no reaction with tinct. ferri perchlor. A liberal carbohydrate diet was ordered, but he had little appetite and took only about carbohydrate 30, protein 36, and fat 50 in twenty-four hours. Thereafter he became somewhat restless and drowsy. Thirty-six hours after admission he suddenly collapsed, the pulse becoming imperceptible. He recovered slightly under stimulation, but improvement was transient and he died ten hours later. At no time was there any suggestion of air hunger, the breathing throughout being easy, regular, and natural. A positive tinct. ferri perchlor. reaction was never obtained in any sample of urine. Another case seen more recently, a man aged 50, gave a history of having taken little food for three weeks prior to coming under observation. The urine contained much sugar but no acetone or diacetic acid; the blood sugar was over 0.4 per cent. There was some twitching of the muscles of the neck and upper chest and the breathing was slightly Cheyne and Stokes in type. The pulse was rapid and of poor quality. Despite stimulation, liberal carbohydrate, and insulin in large doses he died, apparently of cardiac failure, thirty-six hours later. Cardiac failure was certainly an important factor in these cases and was a complication for which one must watch in all severe diabetics. Two of the cases admitted for insulin treatment showed signs of cardiac weakness, so that the routine "starvation" diet until sugar-free had to be stopped and replaced by feeding plus insulin.

science of physiology and its clinical applications, and at fitting the medical student a sound practical basis for his clinical work when he passes into the hospital. Thus, under the heading of gastric secretion, the production of a gastric systola and the method of obtaining pure gastric juice are considered; also the formation of the stomach pouch for the study of the nervous mechanisms of gastric secretion and the chemical action of food substances. Following on this are directions for the collection of gastric juice in man and the analysis of the test meal, the student learning how to determine the total acidity, the free hydrochloric acid, the combined acid, the pepsin, and serum, and the hydrogen ion concentration, and to apply the test for lactic acid. Again, under the heading of the renal sense, in addition to matter of theoretical interest, are studied such practical subjects as the use of the perimetre and the mapping of the field of vision, the pupillary reflexes, the determination of the dioptric strength of a lens, the determination of the power of accommodation, and the use of the ophthalmoscope and retinoscopy. Similarly, with all the great organic systems, the lessons are so arranged as to afford both theoretical and practical aptitude, and the student who takes his purely medical studies, that his power of assimilating material facts is vastly facilitated.

It is probable that in the teaching of pathology there is too great a tendency to regard each disease as an entity, having its own particular cases and lesions, characteristic and characteristic symptoms indicating its presence. That point of view is, doubtless, correct, but it is equally important that the habit should be acquired of regarding disease as a deviation from the physiological norm, and the practical course laid down by the authors will enable the student who follows it to approach the study of disease from that standpoint. Professor Starling, in his introduction to the book, states that "the time allotted to physiology is too short. It seems ridiculous that at the present time students should be expected to learn the whole of anatomy, physiology, and pharmacology in two years, whereas thirty years ago they devoted two years to the same subjects, when we consider that, in the meantime, the content of physiology, as well as the importance of its practical study for clinical medicine, have increased three or four times. The effect of shortening the curriculum has been to send the student into the wards tired and confused, and to rob him of that freshness of outlook and keenness of interest which are essential if he is to make the most of his clinical studies."

HEALTH AND THE HUMAN SPIRIT.

The quality of Dr. KATIA MOSKOWSKA'S little book *Health and the Human Spirit* may be measured by a quotation from its closing pages: "What is truth? The question is no longer unanswerable. We need only to turn and look at the continuity of progress of which we are a part, all that wonder of activity which is going on around us and in us." From which it appears that the author is an optimist. But he is even more hopeful than this quotation implies, for while admitting that answers will not come easily, he yet thinks that "we may even find an answer to the question as to what the future holds for man's vitality when it can no longer use the body as a means of expression." Putting aside religious considerations, we may perhaps prefer to think of mankind as a collection of personalities rather than of vitalities. We cannot think that vitality is a word happily chosen to connote the human spirit; it does not, for one thing, differentiate a man from a black-beetle. For Dr. Moskatrat the health and salvation of the human spirit depend upon the acquisition of a knowledge of radiotelegraphy: the other sections have been revised. The knowledge of the process of life, and again, "it is becoming clear that the new faith will rise out of inter-pretation by consciousness of things human and things natural, of fact and reality, and will call to devotion not to some superhuman idol, but to the expansion of human life."

*Health and the Human Spirit*. By K. W. Moskatrat, F.R.C.S., Edin. London: J. Murray, 1921. (Supp. roy. 16mo, pp. 152, 5s. net.)

NOTES ON BOOKS.

We welcome the second edition of Dr. ALBERT CROTT'S work on *Thyroid and Thyrimus*; the first edition of which was reviewed in the JOURNAL nearly five years ago. Every chapter, as we remarked at the time, shows an intimate knowledge of the subject, which is dealt with exhaustively from the medical, surgical, and pathological standpoint. There is, unfortunately, another side to the picture. In spite of the fact that the writer asserts in the preface that he has tried to take into consideration the criticisms of the first edition, the work is still marred by the defects to which we drew attention. There is the same inexcusable confusion in the arrangement of the first half of the book, and the English is still sadly in need of revision, nearly all the errors which we noticed before being reproduced. Lastly, although in deference to our suggestion a bibliography has been added, it is bibliographical style is not uniform, many names and references are in incorrect style, and many names, some of considerable importance, which are mentioned in the text are omitted.

The medical practitioner is not usually a man of much leisure, and he is apt—quite rightly—to devote what leisure he has to such lighter forms of recreation as golf or bridge, although there are, of course, a goodly number of exceptions. Most of the stories are about the varying fortunes of farmers, shopkeepers, and peasants—or wills, sales of farms, bargains, and bankruptcies. None, indeed, appears from these stories to play a very important part—if not the most important part—in the lives of Ulster folk. There are also, however, some pleasant little sketches of scenes scattered among the stories. The author must be congratulated on an interesting and amusing volume of stories, but he would probably reach a wider public if he were content to keep the dialogue for dialogue only, as he does very successfully in one story.

The sixth edition of the classical work on therapeutics edited by Professor J. SCHWABE differs from the last, which was published in 1921, mainly by the addition of a section on obstetrical methods by Professors von Jasschke and Siegel and a considerable enlargement of the section on radiotelegraphy: the other sections have been revised. The Professor Zuckerkandl, has been revised by Professor E. König of Wetzburg.

large injection of insulin which alone was available at that time, even over the abdomen. To-day, as the result of prolonged insulin treatment, the boy was running about the ward and in appearance compared not unfavourably with many of his fellows. His weight was now 32 kilos (5 st. 8 oz.), diet carbohydrate 70, protein 80, and fat 100, insulin dosage 30 units a day, and he was sugar- and acetone-free with a blood sugar of 0.15 per cent.

All results proved abundantly the great value of insulin in acutely ill patients. It would seem to hold out hope of cure in "early" cases and undoubtedly it alleviated the lot of the more chronic. Unfortunately the treatment was expensive, and for hospital cases the "Allen" treatment must remain for the present the most useful despite its somewhat unsatisfactory results. It was a doubtful kindness to a patient to assure him that a diet had been found for him which would keep him well and satisfied provided he obtained a drug which he was unable to afford and whose administration was outwith his capabilities. In conclusion, Dr. Rennie referred briefly to another chart, which illustrated one of some experiments which were made in the administration of insulin by inunction following Telfer's rabbit experiments recently recorded. The chart showed the blood-sugar curves obtained in a diabetic following a meal (a) without insulin, (b) with insulin injected in the usual way, (c) with insulin inunction. No reduction in blood sugar was found, a result confirmed on other occasions both with an ointment of crude insulin prepared by Dr. Telfer and similar to that used by him on rabbits and with other preparations. No dose of insulin which Dr. Rennie was able to give in that way—and he had endeavoured to give 100 units in one inunction—produced any effect upon the blood sugar. Insulin appeared not to be absorbed through the skin.

Dr. E. P. POULTON (London) spoke of the effect of insulin on relatively mild cases—those which became sugar-free on diet restriction. An attempt had been made to discover if any increase of tolerance took place after prolonged treatment. The rise of blood sugar was estimated after giving 25 grams of sugar, and the experiment was repeated after a period of treatment. The quantity of the sugar was chosen so that in-patients felt satisfied; about 40 calories per kilo was allowed; the protein was about 1.5 grams per kilo, and during treatment the patients were walking about. After receiving 60 units a day for thirty days one case showed a gain in weight, but no evidence of improved tolerance. In one there was distinct improvement, in another perhaps a slight improvement; in one case after eighteen days' treatment there was a slight but definite improvement.

Dr. OTTO LEYTON (London) referred to the probable curative properties of insulin in diabetes mellitus of comparatively recent origin, and due to defect of the pancreas. Many had found that overworking the cells of the islets of Langerhans was followed by progressive degeneration. They had reason to think that whatever cause led to the sudden onset of diabetes mellitus, the destruction of the pancreas was, as a rule, not complete; some cells survived unchanged, some were destroyed, and some had their vitality reduced. Evidence of this consisted in the fact that a dog with a small fraction of pancreas, but of healthy pancreas, might be submitted to a general anaesthetic time after time without causing any recognizable deterioration of the pancreas, while the tolerance of the majority of diabetics was decreased by the administration of chloroform, ether, and sometimes of nitrous oxide. When there was a probability that damaged cells were present, it was thought worth while to attempt to nurse them back to health by rest. Rest of the pancreas was procured by giving sufficient insulin to maintain a slight hypoglycaemia. This might lead to symptoms of hypoglycaemia, but these were controlled by the administration of sugar. There was reason to believe that the tolerance of early cases improved. An attempt was being made at the London Hospital to obtain evidence by comparing the curve of the blood sugar while and after giving dextrose intravenously over a period of three hours, before and after a course of treatment.

Dr. A. P. THOMSON (Birmingham) said that he treated over 30 cases of diabetes with insulin, and he observed definite increase in tolerance after a period of treatment in two cases that had been previously rigorously dieted for a considerable time. He mentioned these specifically, as Dr. Banting himself seemed to doubt whether such a thing could occur. As the result of his experience Dr. Thomson believed that it was quite impossible to treat diabetic patients who could not learn to take care of themselves to a large extent or those patients who lacked determination necessary for the limitation of their diet, unless, of course, continuous control could be arranged. Hospital practice was frequently disappointing. With reference to the value of blood-sugar estimation in control of treatment, Dr. Thomson found that it was possible in the average case to get along with very few estimations during the preliminary period of standardization in a nursing home, and that afterwards he had found them necessary providing the urine was examined frequently enough and that the diet was properly controlled. He believed that the liability to toxic symptoms after insulin decreased with the improvement in the condition of the patient. He mentioned as unusual complications in insulin treatment the occurrence of acute cataracts in a patient who was otherwise doing well and two instances of transient haematuria after large doses. He agreed with Dr. Leyton that the so-called hypoglycaemia crisis frequently occurred when the blood sugar was above the normal, and he believed that the sudden change in level was more important than the exact value.

Dr. F. A. ROSEN (Exeter) detailed an incident in the case of a male patient, aged 54, whose general condition, blood-sugar curve after glucose meal, and acidosis estimations showed diabetes of a considerable severity. He had some few months ago had diabetic coma and there was considerable albuminuria. Starvation was badly borne, so that on the fourth day despite considerable glycosuria he was placed on a diet of about 600 calories containing 16 grams carbohydrate, while insulin 20 units per diem was commenced. On the third day of this diet the insulin was increased to 30 units given in three equal doses. The urine was closely watched for disappearance of sugar. On the fifth day the urine at 9 a.m. contained sugar, and the blood sugar on the day preceding was 0.20. Lunch was taken at 1.15 preceded by insulin. An hour later he expressed himself as feeling "very fit." A quarter of an hour later he was found comatose—unconscious—with deep abdominal breathing tending later to become irregular (Cheyne Stokes). From the first he was unable to swallow, and glucose per rectum failing in any way to improve his condition, in fifteen minutes or so 2½ drachms of glucose in a pint of saline were administered intravenously. Ten minutes after commencing the injection he began to yawn, and in half an hour could speak and thereafter quickly recovered. A urinary specimen passed at noon that day was found to be sugar-free, this being the first time it had been sugar-free since he had come under observation. The incident was related (1) in support of the contention that at present all patients requiring insulin should be under hospital conditions of observation and treatment until their basal dietetic requirements and proper insulin dosage had been determined, and (2) as emphasizing the advisability during this initial period of frequent blood-sugar determinations inasmuch as hypoglycaemia in this case supervened within five hours of cessation of glycosuria with a moderate insulin dosage.

LIEUT.-COLONEL E. E. WATERS, I.M.S., asked Dr. Banting if the temperature at which insulin was stored had any effect on its potency; and Dr. CLARK BEGG (Swansea) inquired what instructions should be given to patients on leaving hospital. Should they be sugar-free or discharged with a small degree of glycosuria?

#### Dr. Banting's Reply.

Dr. BANTING, in reply, said that the cause of deficiency of the islets of Langerhans was not known. Patients requiring continuous treatment were trained to give their own injections. Larger doses of insulin were always

25 and no deaths; the white and red lead manufacture few deaths, are attributed to the use of paints in various industries. Attention is directed to the disproportionate mortality in pottery cases, as compared with the rest, and to the difference in the pottery figures themselves since the Workmen's Compensation Act of 1866 came into force and allowed compensation for death due to such sequelae as chronic Bright's disease. The differences are graphically shown in a case mortality table. Another interesting point is the higher paralysis (12.2 per cent.) among men than among women (4.7 per cent.), and the converse in cases of encephalopathy, which shows 2 per cent. for men and 3 per cent. for women. Reference is made to the increased safety in the rubber tread through being able to purchase the necessary lead already incorporated with rubber and other materials instead of introducing it dry into the mixer. The use of oxy-acetylene flame in the breaking-up of battelships has again accounted for a number of cases. Leaders showing the dangers of lead absorption and the means of preventing this have been drawn up for the use of the Joint Industrial Councils of the Printing and Allied Trades and the Paint and Decorating Trades respectively. No cases of arsenic or phosphorus poisoning were notified, but there were 6 cases of mercurial poisoning, with 1 death, and 3 cases of toxic jaundice.

#### Lanthrax.

Lanthrax accounted for 45 notifications, 5 cases being fatal. That only three notifications came from Bradford is ascribed to the disinfection of East Indian goat hair at Liverpool. The mortality is only about half what it was prior to 1906 owing to modern expeditious treatment with Sclero's serum. The Advisory Committee of the International Labour Organization resolved, in December, that hair for brush-making and upholstery should be disinfected before using industrially, and that hair and wool in certain textile purposes should also be so treated except in certain specified circumstances; also that hocks should be dealt with by compulsory notification, and verification, isolation, disinfection, preventive inoculations, and complete destruction of infected carcasses. This committee recognizes the impossibility of complete disinfection of hides and skins at the present time, and strongly recommends grants-in-aid for international research in this direction.

#### Poisonous Chemicals.

Forty-two cases of chrome ulceration had been reported, 10 in the manufacture and 32 in the use of potassium or sodium chromate, but Dr. Legge anticipates a diminished incidence with a better understanding of the Chrome Dyeing Welfare Order by the workers. There were 32 cases, with 3 deaths, from epitheliomatous ulceration, and under this heading reference is made to the value of the discussion at the Glasgow meeting of the British Medical Association in showing the importance of the figures now available in their bearing on the experimental work being carried on. It is stated that more and more time has to be devoted by medical inspectors to investigations of dermatitis; celluloid substitutes, shellac varnishes, sugar, teak wood, "Accelene" (rubber vulcanizer), cracking of Brazil nuts, orange peeling, labracting oil, and phosphorus sesquisulphide all produced cases during the year.

Cases of poisoning from accidental escape of fumes and gases were 194, of which 20 proved fatal, carbon monoxide with 111 and 14 deaths heading the list. Detective fittings and inadequate ventilation of gas stores accounted for 28 cases of CO poisoning in workrooms. Of the 10 cases of chlorine poisoning, 6 occurred from the use of cylinders of this gas in the bleaching of flour. Sulphuretted hydrogen, ammonia, benzene derivatives, naphtha, petrol, methyl carbonyl, carbon bisulphide, and sulphur dioxide were other causes of poisoning. Owing to a request from the International Labour Office an inquiry was made into the alleged ill effects of photo-engraving, but occurrence of serious conditions having undoubtedly been brought about since the year.

#### Siliceous Dust.

Dr. Middleton reports on his investigations into the dust content of the atmosphere of workshops for the grinding of metals and cleaning of castings. Using the very effective dust-counting apparatus recently invented by Dr. J. S. Owen of the Meteorological Office, Mr. Minbury, the collector a very large number of samples from the air of workrooms in which these processes are carried on, and his results, being the first obtained from this method of collection, are necessarily important. He confirms the view that silica derived from sandstone or other natural rocks is the prime cause of fibroid phthisis and shows that it is the very small particles, invisible under ordinary conditions of indoor illumination, which causes the damage. These minute spicules diffuse through the air and are thus dangerous to others as well as to the actual grinder. He states that they are thrown off very extensively in wet sandstone grinding and that the dressing of grindstones causes an intense saturation of the atmosphere. A copious application of water at the point of contact of metal with abrasive and the association of dry grinding with an efficient exhaust are regarded as the most effective means of securing a minimum pollution. The cleaning of castings does not appear to be associated with the evolution of large quantities of fine silica dust.

#### Weight Carrying by Women.

Dr. Eileen Hewitt reports on her investigations into the comparative physiological costs of different methods of weight carrying by women. She used in her experiments the Douglas-Haldane method of collecting, measuring, and analysing expired air. The carbon dioxide output and oxygen consumption at different times were thus determined and the energy expended in calories was calculated. Various methods of carrying were used in the experiments, and she concludes that no one method should be employed continually when transporting weights of over 35 lb. She states that heavy loads carried at the front, especially when helped by a neck strap, tend to cause round shoulders, and that shoulder carrying on a board tends to create lateral curvature. Adolescents should not use this latter method and adults should learn to utilize each shoulder alternately. The method of loading and laying down is believed to be of great importance, and the unloading level should, as near as possible, be in line with the shoulder. So far as could be ascertained, the physiological cost of work is not objectively affected by menstruation.

in bringing this about.

#### Industrial Hygiene and Welfare.

The standard of first-aid and ambulance arrangements under Welfare Orders is considered to be well maintained. There is, however, complaint of irregularity in keeping up the supply of sterilized dressings in first-aid boxes; also Dr. Henry has noted that of the ambulance rooms, under the supervision of a medical man, so that cases in charge of a trained nurse, out of 42 visited, only 5 were found a practice where such are stocked in the ambulance room. It is also thought that much more propaganda work is needed. Of the 267,564 young persons examined for certificates of fitness a table shows that the detailed diseases and physical defects demanded the rejection of 5,318 and the imposition of conditions on 6,673, also that attention was directed to unsuitable attire (and loose hair) in 1,031 cases. It is stated that the increasing general interest in the effects of industrial employment on health is manifest in the greater importance attached by both employers and employed to the examinations by the certifying surgeons. It is, however, regarded as unsatisfactory that the surgeon's function does not extend to re-examinations. Note is made of the very desirable co-operation existing between welfare supervisors and certifying surgeons and the valuable assistance rendered by Dr. Henry

etching of stainless steel.

introduction of specially designed baths. A very similar result followed an investigation by Dr. Middleton into the

mechanical masseurs as have been introduced as a substitute for the finger; for we are probably all agreed that nothing is so effective for the carrying out of massage as the finger. I refer rather to electrical stimulation of the prostate by means of an electrode placed within the rectum. An excellent electrode for this purpose is that which has been made for me by Messrs. Schall, according to instructions supplied by Dr. E. P. Cumberbatch. It consists of a metal spoon with rounded edges mounted on a vulcanite rod and with a screw for attachment to the source of electricity. Although a static machine, such as the Wimshurst, is probably the best source of current for use with this electrode, a more convenient one is the physio-faradic wave apparatus, supplied by the Medical Supply Association, which gives a slowly interrupted faradic current, the interruptions being spaced at intervals of about one per second. This instrument is at present in use in the venereal department of St. Bartholomew's Hospital for the treatment of cases of chronic prostatitis. It is employed in certain cases as a substitute for prostatic massage, with very satisfactory results. Its efficiency is shown by the amount of secretion that appears at the meatus during its use. The precise action of the current is, however, a matter of doubt, for it is generally agreed that a faradic current has no direct action on unstriated muscle. If this is so one can only suppose that the stimulus to the contraction of the prostate is supplied by the vigorous action on the striated muscles in its neighbourhood. However, it is interesting to note in this connexion that Wallace has asserted that in addition to unstriated muscle the prostate contains a small amount of striated muscle. In spite of the somewhat alarming appearance of the electrode the treatment is not in the least distressing, and the discomfort experienced is very little greater than that usually complained of in the case of digital massage. I am aware that others have tried electric massage before me, notably Hogg and Courtride, and that the majority of those who have experimented along such lines have ended by abandoning electrical in favour of digital massage. Nevertheless, I am convinced that massage of the prostate is of such overwhelming importance in the treatment of prostatitis that no efforts should be spared to explore every possible method of carrying it out, and I mean to persevere with the treatment.

That massage of the prostate causes an absorption of bacterial products by the blood stream is rendered evident by the reaction that follows it. This reaction is generally noted on the two days following the treatment, the patient complaining of lassitude, headache, fever, increased local discomfort, and, where the prostatitis is associated with chronic rheumatism, of an increase of pain in the joints. On account of this it is advisable when vaccine therapy is being employed, as well as massage, to arrange that the injection of the vaccine does not coincide with the massage, otherwise a double reaction may be provoked. It is true that all cases do not show this general reaction after massage, but it occurs sufficiently often to show that the massage has an important general action in addition to its local one.

#### *Dilatation of the Posterior Urethra.*

Dilatation of the prostatic urethra by large-sized bougies, or by special dilators, is another therapeutic measure that is extensively used in the treatment of chronic prostatitis. The action is generally considered to be a mechanical one, the pressure of the instrument on the prostate resulting in the expression of the retained contents of the follicles. Again I am inclined to differ from the orthodox view, and to express the opinion that the bougie's action is an indirect one exerted through the musculo fibre of the prostate. For this reason as well as for others I am strongly against any attempt being made to dilate the prostatic urethra by means of a Kollmann's dilator, or by any other instrument than a bougie. No instrument has yet been invented, or is likely to be invented, that is capable of dilating so irregular a cavity as that of the posterior urethra, and the use of a curved Kollmann for the purpose can only result in trauma.

I am inclined to think that already a reaction is taking place against what I may term the Great Metallic Age of the history of the treatment of gonorrhoea. For the last fifteen years the ingenuity of urologists has been employed on the invention of a whole armoury of instruments for the detec-

tion and treatment of urinary conditions, and the gonococcus has been ruthlessly pursued by the enthusiastic inventors of various forms of urethroscopes, dilators, electrical cauteries, electrodes, flushing bougies, and a host of other instruments. But the more closely one keeps in touch with the pathology and bacteriology of gonococcal infections the more forcibly it is impressed upon one that final victory over these infections will not be achieved through the instrument-maker but through the biochemist or the bacteriologist. Far be it from me to underrate the value of urethral instruments in the precise diagnosis and treatment of the more superficial lesions of gonorrhoea. I would even concede that they are of service in the treatment of more deeply placed infections such as prostatitis; but while recognizing the aid they lend, I am convinced that there is a very grave danger at the present time of employing instruments too freely, especially in the case of posterior infections, and of thereby actually prolonging the course of the disease we are attempting to cure.

#### *Treatment through the Blood Stream.*

Under this heading I would include such measures as vaccine therapy and the use of intramuscular or intravenous injections of drugs. Of vaccine therapy I cannot speak with any great enthusiasm, although, like everybody else, I have had cases which have undoubtedly received benefit from the use of an autogenous vaccine. In those cases in which prostatic massage produces a reaction I do not as a rule use a vaccine, as I consider that massage is an excellent substitute. It is in the very chronic and stubborn case in which a reaction does not occur after massage that the use of a vaccine is specially indicated, and in the same type of case I not infrequently employ "shock therapy." We have probably all had cases of this description which have improved materially as the result of an added infection such as an attack of influenza, and I am sure that "shock therapy" has a definite sphere of utility in the treatment of chronic prostatitis.

Of the various drugs that have been employed in the treatment of chronic prostatitis I can only speak from personal experience of sulfarsenol and of silver-salvarsan. The results obtained from their employment in obstinate cases, and especially in cases complicated by rheumatism, have been such as to encourage me to continue their use, for it is by working along such lines and by increasing one's knowledge of the bacteriology of gonococcal infections that I anticipate that future progress will be made.

#### *Diathermy.*

At the last meeting of this Section I reported favourably on the use of diathermy in the treatment of gonococcal infections of the cervical canal. Since that time we have turned our attention in the venereal and electrical department of St. Bartholomew's Hospital to the use of diathermy in chronic prostatitis. The applications have been made by means of the spoon-shaped rectal electrode already described. The cases submitted to treatment have been those in which the gonococcus was either present when treatment started or had been found at some previous date. The majority of cases suffered from rheumatism as well as from chronic prostatitis. The results, on the whole, have been very satisfactory, and have already been published by Dr. E. P. Cumberbatch. Some of the cases were referred to the electrical department on account of the joint affections alone, but it was found that improvement in the joints was more rapid if the prostate was treated at the same time. Indeed, in certain cases diathermy to the joints was abandoned and attention wholly centred on the application of diathermy to the prostate. The treatment has the advantage of being painless, and even when it fails, as it certainly does in many cases of staphylococcal infection, no harm has been inflicted on the urethra. Throughout the treatment a thin mucous discharge occurs from the urethra, but this generally disappears after the applications have ceased.

#### *Surgical Measures.*

Although the vast majority of cases of chronic prostatitis yield finally to the above-mentioned methods of treatment, I can recall some five or six cases encountered during the last twelve years in which I have had to have recourse to

| 121                          | ... | GENERAL PRACTICE AND ITS UNBLAZED TRAIL. By   |

“General practitioners are the infantry of the medical army, we are its first line of defence and offence against disease. To us alone is given the opportunity to watch disease from its beginning, though it is gradual development. Then why is it that we, whose clinical opportunities are so untrivalled, take so little part in the advancement of our art? Why is it that only here and there a heroic soul arises with a genius for hard work and an unquenchable persistence in seeking answers to all the whys and wherefores that come into (or should come into) our minds as we watch diseases and see their symptoms and physical signs? Sir James Mackenzie is a living monument of what can be done if only we have the will to do, and I doubt if any one of us works under greater difficulties than he did whilst he was patiently working out the causes and prognoses of irregularity of the heart beat. We are handicapped, and we handicap ourselves.

We are handicapped in an industrial area such as this by the mass of work we have to undertake in order to live. In the rush of each day we lose the power to think clearly. We think loosely and only little, when we should do so (leisure) and much. We give a condition a name and are then quite happily convinced we know all about it. Sometimes this is so much the case that when symptoms or signs arise and we tell us our label is wrong, either we do not hear or are inclined to look upon them as rather impertinent vagaries of the condition we have baptized, and only tardily—perhaps too late—listen to the story they have to tell.

Habitual and careful note-taking will get rid of this difficulty. Some may say there is not time to do this.

There is time. True, it takes a little longer when one first sees a patient, but once the record is made it is there for all time. When one sees the patient again, one takes up the record where one left it: the facts are there, no need to go back to mind. We must concentrate on the patient until they come back to mind.

on a thing before we can write about it. If a diagnosis is difficult, careful methodical notes will help to solve the problem. We can go over them at our leisure, notice what

\* Abstract of Presidential Address to the Staffordshire Branch of the British Medical Association.

we have left undone, where pieces of what is often a jigsaw puzzle are missing, and so perhaps be fortunate enough to complete the picture. When a patient dies we can go again over the whole story, try to see when and how the train of events began which ended in death, where perhaps we went wrong, and what to do or not to do in a similar case in future. I know my own notes are hopelessly inadequate, but nothing has been a greater help to me in my own practice and in nothing, on balance, all things into consideration, has saved me so much time. I would like to lay especial stress on one point: When making notes of a case it is of the greatest importance to record anything that seems anomalous or unusual. We should never ignore an observation just because it does not appear to fit into the picture as we imagine we ought to see it.

We are handicapped, again, by the fact that we rarely see a *post-mortem* examination of any case that has been under our care and are thus unable to check our clinical diagnosis. The "last chapter" of our cases is often mere speculation. The ideal would be, in all cases of doubt, one death certificate to be given by the medical attendant for burial, and one (which, of course, would have to be a "condemned" one), by a pathologist after autopsy for registration, for the benefit of the medical science in general, and for the benefit of the "accessory before the fact" in particular. I can imagine nothing which would be of so great a stimulus to medical progress as a more frequent opportunity to "look inside" and to be able to compare clinical and pathological findings. This may be an unattainable ideal; it certainly terrifies one by the cruelty of the truth it would at times bring to light, and its general acceptance is for many years to come unlikely. Still many things are accepted now, many burdens borne with only passing comment, which would have seemed just as impossible of social acceptance or of suffering a few years ago. Let us discuss the idea amongst ourselves, then, with our patients, especially educated patients to avoid impositions and compromises with those of the hospital class; a necropsy is merely an operation after death. Let us ask for a necropsy, however, when we think any good could come of it, or there is any chance of consent. This would put us on the right road; the rest, perhaps, would follow in time.

Again, we need a closer co-operation between the general practitioner and his local hospital. As a matter of routine, reports on all cases admitted should be sent to the doctor, under whose care the patient was before admission, giving date of admission, diagnosis, treatment, and ending at any operation, the result, date of discharge or death—if the latter the finding at necropsy. When possible, an opportunity

We still await the appearance of a safe and reliable specific vaccine or serum. Foreign proteins—electrargol, sulfarsenol, etc.—have been successful only in the hands of a few. But expectant treatment will in the majority of cases bring about a subsidence of the acute symptoms in a week or ten days, and thereafter the vesicles can be treated by regular massage until their expressed contents are free from gonococci and pus. I have already spoken of the important causative factor, reversed peristalsis starting from the posterior urethra. Could not this be used in treatment—for example, might we inject into the posterior urethra an antiseptic sufficiently irritating to set up this reversed peristaltic wave but not strong enough to damage the delicate epithelial lining? This is a suggestion which I have not tried.

Vesiculitis has, in my experience, been a comparatively rare complication. I have been unable to understand the contention, so vigorously maintained by many American writers, that vesiculitis is a constant accompaniment of gonococcal rheumatism. I have found it present only in a minority of these cases, and even then not the vesiculitis, but rather the accompanying prostatitis has proved to be the main disturbing factor, both as regards causation and amenability to treatment. If one compares gonococcal infection of a seminal vesicle with a gonococcal salpingitis, one finds a main point of difference, which is that a gonococcal vesiculitis has not the same tendency to closure of its exit. In salpingitis closure of both ends of the tube and its conversion into a retention abscess is the rule, and while this may occur also in a vesiculitis it does not happen in the majority of cases. In most cases some drainage is maintained during the acute stage, either by overflow or by involuntary emissions, and after the acute stage drainage can be ensured by massaging the vesicles. Even in cases where closure of the vesicle duct does occur the same sequence of events as takes place in salpingitis may be anticipated. After an acute process lasting a week or ten days the pus sac becomes sterile owing to the destruction of the gonococci by the products of their own metabolism, and thereafter absorption of the surrounding inflammatory exudate and of the vesicle contents gradually takes place. This process of repair can be assisted by appropriate treatment—namely, rest, diathermy, hot rectal irrigations, and rectal suppositories of glycerin.

As regards surgical treatment, so far I have not personally encountered a case which demanded it; but just as in gonococcal salpingitis rare cases occur which call for operation in the acute stage on account of the hyperacute reaction, so in gonococcal vesiculitis we may at any time require to operate. This is a very different viewpoint from that of the American writers to whom I have already referred; their preference seems to be for a vesiculectomy or a vesiculotomy whenever a diagnosis of vesicle involvement is made, and some seem to favour an exploratory investigation in all cases of gonococcal rheumatism. A review of published statistics of operation cases has failed to convince me that the results achieved are superior to those we get without subjecting our patients to surgical risks.

One operation requires, perhaps, some special consideration—namely, Belfield's vasostomy for irrigation and drainage of the seminal duct and vesicle. Under local anaesthesia the vas is isolated from the other structures of the spermatic cord, pressed against the scrotal skin, and fixed by passing a curved needle behind it. A half-inch incision is made through the skin and coverings of spermatic cord, the vas is exposed, and a small opening is made into the canal. A blunted hypodermic needle is passed into this minute channel, and a watery solution to the extent of 20 or 30 minims of any desired agent may be injected. The fluid will pass along the vas and distend the seminal vesicles. Belfield maintains that by this method not only can chronic infection of the vesicles be rationally treated, but an impending epididymitis may be aborted or recurrent attacks prevented. The difficulty seems to be to find an antiseptic one or two injections of which will sterilize the infected vesicle without damaging the very delicate epithelium of the vas and of the vesicle sacs.

To sum up, my views on operative treatment are that only on a very rare occasion will it be necessary to drain

a vesicle abscess from the perineum; and as regards Belfield's vasostomy—it is an interesting suggestion, but I do not know of any preparation one or two injections of which can be relied on to be effective and non-destructive.

#### DISCUSSION.

Mr. DAVID LEES (Edinburgh) said:

I have listened with great interest and pleasure to the papers on vesiculitis and prostatitis, and I should like to congratulate Mr. Kenneth Walker and Dr. Watson on their clear presentation of a very difficult subject. Although I am in general agreement with the majority of their views there are one or two points on which my clinical experience is at variance with their views, and one or two questions which I should like to ask. It is, I think, a healthy sign that there should be differences of opinion among scientific workers on any given subject, in that it stimulates us to search for something better in the way of treatment, for most of us will admit that we have not yet reached finality in the treatment of the complications of gonorrhoea even with diathermy. As Dr. Watson has dealt more with the preventive aspect of the subject than Mr. Kenneth Walker it is, perhaps, better to discuss his paper first.

I do not think he stresses enough the function of rest in preventing the extension of the infection from the anterior to the posterior urethra, nor the function of diuresis in establishing drainage of the infected area. Hard work entailing mobility of the pelvic and perineal muscles and the old familiar cotton-wool plug are two of the outstanding causes of posterior urethritis. He spoke also of the value of detoxicated vaccines in the treatment of established vesiculitis, but in my experience these vaccines exercise a greater influence in the early stages in ameliorating the course of the disease and in preventing the onset of complications, and are invaluable in acute gonorrhoea if carefully given and their action in each case watched.

On the question of urethral lavage I am afraid that I do not altogether agree with Dr. Watson, but not chiefly for the reasons which he puts forward—the uncertainty of diagnosing a posterior urethritis during its incubating stage, and the lack of certainty of confining the infection to the anterior urethra by treating the infected area alone. By careful methods it is possible, I think, to diagnose most cases accurately, and in the large majority to confine the infection to the anterior urethra if treated early. My chief reason, however, for differing from him is that in the majority of cases of early anterior urethritis the treatment is carried out by the patient or by a more or less skilled orderly, and I think the trauma to the urethra of unskilled lavage or forcible lavage is a big factor in setting up complications. I have no objection in any case to the *gravel* lavage of Janet in competent hands, but until I am satisfied that the patient can do it comfortably and has acquired the art of so doing it, it is better left alone by him in anterior urethritis, except when he is seen at hospital or in the consulting room under expert guidance. I agree with Dr. Watson that in established posterior urethritis it is always an essential, apart from the few hyperacute cases, in which it is preferable to wait for two or three days before commencing it. Of the antiseptics advocated by Dr. Watson I do not find acriflavine any more potent or any less irritating than either alkaline potassium permanganate or albugin, and none of those three is so potent or causes so little irritation as mercurochrome 220, which retains its potency in urine but has the same objection in private work as acriflavine—namely, its staining propensities. Recently I have had quite favourable results with nizin, 1 in 250 to 1 in 500. There is one other point in connexion with lavage which Dr. Watson mentions—namely, the interval between its applications. On the analogy of the eye infection I am strongly of opinion that the more frequent the urethra is washed out in anterior urethritis and the less the pus is allowed to accumulate, the more quickly will you eradicate the infection and the less will be the damage to the surface epithelium if the antiseptic is not too strong.

I am in complete agreement with Dr. Watson as to the value of atropine in treatment, but prefer larger doses—1/75 grain, and always in the acute stage combine with it

The by-laws empower the Council either to fill such vacancies itself or cause them to be filled by means of an election by the Branches concerned. The Council has decided

4. Never to pass any instruments into the bladder in a recent uncomplicated case. In the army my experience was 13 per cent. of all cases of gonorrhoea had epididymitis—6.5 before admission and 6.5 after—and many of the cases in the latter portion were due to treatment. By keeping to the rules I have mentioned I very rarely see epididymitis after treatment has commenced.

The symptoms of chronic prostatitis and vesiculitis can almost always be relieved by treatment, but these conditions are practically incurable if the test of cure is complete absence of pus cells in the secretion expressed by prostatic massage. It is possible to divide them into two classes. First there is the man who without symptoms of any kind has pus in the expressed secretion. He gives a history of gonorrhoea some years previously and generally the only thing he complains of is an occasional discharge; or else he wishes to be examined to find out his fitness for marriage. Treatment is essential in these cases, as many of them will develop sexual or urinary disturbances or metastatic lesions later on. For them I prescribe prostatic massage for three months. Although most of them will still have pus at the end of this time, I think the treatment is beneficial and likely to ward off later symptoms. The other class may have a persistent urethral discharge, frequency of micturition, iritis, muscular rheumatism, fibrositis, pain during sexual intercourse, blood-stained ejaculation, and neurasthenic symptoms. Treatment should be continued till these symptoms are cured. The patient should also be instructed to live a careful and regular life, avoiding alcoholic and sexual excess, constipation, and other irregularities. For years I have relied on massage alone, but latterly I have combined it with application of heat by a water-heated applicator in the rectum. Water at a temperature of 120° F. flows from a container through the applicator for twenty minutes. The heat brings an increased flow of blood and lymph to the tissues and a much greater quantity of fluid can afterwards be expressed by quite lightly applied massage. Dilatation of the prostatic urethra by solid instruments or by mechanical dilators is, in my experience, useless, if not harmful. Certainly it is so with a Kollmann's posterior dilator. In the first place, it is only too easy to produce severe damage to the mucous membrane and it does not dilate the urethra. A few years ago I experimented with four blades the same size as those of the Kollmann fixed to the end of a urethroscope. I passed the instrument into the deep urethra and there I saw the mucosa in folds round the blades meeting in the centre of the urethra, but very slight air pressure was sufficient to expand these folds and form a tube. It seems to me that the action of Kollmann's dilator is merely to press certain portions of the mucosa against the deeper firmer structures. I know of two cases where extensive bleeding followed the use of this mechanical dilator.

As regards treatment by vaccines, I do not think that for Class 1 they have any beneficial action at all. I have used ordinary and detoxicated stock vaccines and autogenous vaccines without any effect on the quantity of pus cells obtained in the secretion. For Class 2, with metastatic lesions, I always use Thomson's detoxicated mixed vaccines. The dosage varies for each patient; 2,000 million in one may produce a marked local and general reaction, whereas a much larger dose in other cases has no appreciable effect.

Surgeon Commander PARNELL emphasized the importance of the prevention of secondary infection. He agreed with Mr. David Lees that vaccines (detoxicated) were of most value in the acute early stages. Internally ichthyol (pil. gr. 3 t.d.s.) was of value. Less than 5 per cent. of cases at Haslar had vesiculitis. In metastatic gonorrhoea a chronic glandular prostatitis was more often the infecting focus than vesiculitis. Glandular prostatitis was often asymptomatic, could not be diagnosed by palpation, and was only detected by the microscope. Massage was the great stand-by in treatment—controlled by microscopic examination of the expressed secretions. Sulfarsenol in his hands had shown no appreciable benefits in any metastatic complications of gonorrhoea.

Dr. G. L. EASTES (London) said that he had hoped to have heard the views of bacteriologists on the subject of chronic prostatitis. Vaccines and vaccine treatment had received some hard knocks from previous speakers, but a vaccine to be effectual must be complete. It must include all the secondary organisms as well as the patient's own strain of gonococcus, and in addition, for reasons adduced, the best polyvalent stock gonococcus available; and by the best he wished to emphasize that the age of the stock vaccine should not exceed six months. The secondary organisms must comprise the Gram-positive bacilli so frequently present as well as the cocci. In acute urethritis vaccines were, in his experience, of very great use in effecting a cure without complications.

Dr. JAMES HUDSON (Newcastle) called attention to the frequency with which potassium permanganate was employed in too strong a solution, with the result that the urethral mucous membrane was burnt. In his opinion it should never be used in higher concentration than 1 in 4,000. He had found sodium salicylate of use when given in an alkaline mixture as a means of avoiding such complications in chronic prostatitis and epididymitis.

Mr. KENNETH WALKER and Dr. DAVID WATSON then briefly replied to the questions that had been put to them by the various speakers. Mr. Kenneth Walker agreed with Dr. David Lees that the success of prostatic massage could not be entirely gauged by the amount of discharge that appeared afterwards at the meatus. This amount depended on numerous factors, and sometimes when a patient emptied his bladder a large amount of discharge was found in the distending fluid even although but little had appeared at the meatus.

Sir ARCHDALL REID, in closing the proceedings, congratulated the Section on the excellent discussion that they had listened to, and said he considered that the meeting had been a very great success.

## THE VENTRICULAR COMPLEX OF THE ELECTRO-CARDIOGRAM AS A PHYSICAL SIGN IN CARDIAC PROGNOSIS.\*

BY

J. E. MACILWAINE, M.D., B.Sc., D.P.H.,  
VISITING PHYSICIAN, ROYAL VICTORIA HOSPITAL, BELFAST; FROBENIUS OF MATERIA MEDICA AND THERAPEUTICS, QUEEN'S UNIVERSITY, BELFAST;

AND

S. B. BOYD CAMPBELL, M.C., M.D., F.R.C.P. (Ed.),  
ASSISTANT PHYSICIAN, ROYAL VICTORIA HOSPITAL, BELFAST; VISITING PHYSICIAN, ULSTER VOLUNTEER FORCE PENSIONERS' HOSPITAL, BELFAST.

It is well recognized that our understanding of cardiac disease requires a sound knowledge of the anatomy and physiology of the circulation, and that without such knowledge it is impossible to interpret rationally most of the ordinary symptoms and signs associated with diseases of the heart. It has been the custom, therefore, to impress on the student the necessity of understanding thoroughly the physics of the cardio-vascular system. In recent years electro-cardiography has come to be a method of clinical application in most teaching hospitals, and the student both in the physiological classroom and at the bedside has to understand what an electro-cardiogram represents. As is usual, the novelty attracts the student, but, I am afraid, also somewhat deters the practitioner when it comes to be a question of the use of such a method in general practice. It has been recognized by most of the men who use the electro-cardiograph that its application to-day must be mainly for the purposes of investigation or where an especially full cardiac examination is called for. There is no doubt that, from a prognostic point of view, the electro-cardiogram has a right to be classified as a physical sign of considerable importance. As a physical sign, therefore, the electro-cardiogram has a definite place in

BACTERIAL TYPES AND VARIANTS.

British Medical Journal.

SATURDAY, SEPTEMBER 15TH, 1923.

BACTERIAL TYPES AND VARIANTS.

THE close comparison of individual strains of certain pathogenic bacteria that has been carried out of recent years has brought about a revision of ideas previously current with regard to the constitution of these micro-organisms. Only a short time ago the frontier of pathological knowledge was reached when we were able to ascribe lobar pneumonia to the pneumococcus, cerebro-spinal fever to the meningococcus, and diphtheria and tetanus to the well known bacilli causally related to these diseases. As a result chiefly of the application of modern developments of serological technique, we now know that within each of these pathogenic representatives of the schizomycetes there exist a number of separate groups or types and logically distinct from one another, which appear generally to maintain at any rate the chief portion of their antigenic individuality for an indefinite period, since attempts so far to convert one type into another have failed. The majority of those who have investigated this matter are agreed that each case of pneumonia, cerebro-spinal fever, diphtheria, or tetanus is brought about by a single type of the infective micro-organism; and carriers also exhibit a similar loyalty to the particular type infecting them. The pneumococcus and meningococcus have been the most thoroughly studied from the present point of view; though a considerable number of different types exist, a comparatively small proportion of them are responsible for the majority of the cases.

This internal differentiation of infective units previously assumed to be indivisible is not only of bacteriological and epidemiological interest; for the pneumococcus and meningococcus it has been found to be of cardinal importance as regards success in specific therapy. According to present observations, patients suffering from disease brought about by these micro-organisms are not benefited by serum unless it has been prepared against a strain of exactly the same type as that infecting the patient. In diphtheria and tetanus, on the other hand, where the chief pathogenic factor is a toxin which is readily soluble and diffusible, the question of type is far less important, since here it has been found that antitoxin prepared against the toxin of one type neutralizes that of all the others. From the careful studies of Tullech, however, on the distribution of types of the tetanus bacillus in the wounded during the war it seems possible, if not probable, that the difference in antigenic constitution obtaining between the various types of the tetanus bacillus is not entirely without influence in the genesis of that disease.

Are these types fixed and permanent, or is a process of evolution and natural selection going on, while the older and attenuated go to the wall? At present we have not sufficient knowledge to answer this question. All we can say is that so far as the

THE NUCLEAR ATOM.

EVERYONE who has followed even in the most general way the progress of what may be called the physics of the atom is aware that ideas have been revolutionized and that the revolutionary dates from the discovery of  $\alpha$  rays and of the radio-active elements. We have been aware that physicists during the last quarter of a century have eagerly used the new methods of research these discoveries placed in their hands and probe into the constitution of matter and the nature of the atom, but we shall all be grateful to Sir Ernest Rutherford, who has had so large a part in this acquisition and the interpretation of the discoveries and in indicating the story, directions which research will probably take in the near future. The abstract of his presidential address to the British Association, which he did this is published this week (p. 474), gives a complete account of his general argument with details sufficient to show the line of reasoning followed in relating the astonishing results already reached.

The atom was defined in a popular textbook of the century as the "smallest and chemically-indivisible particle of each element which can exist... unit with other particles either of the same or of different elements, but which is not known in a separate form."

most studied seem to be fixed variants of a parent strain of unknown antiquity. Bacterial variation in one form or another has been familiar for a long time past to bacteriologists, who, when dealing with an organism which, as the result of prolonged culture on artificial media, has lost some of its characters, are accustomed to restore them by the time-honoured expedient—first devised by Pasteur—of passing it through an animal. The systematic study, however, of bacterial variation by serological as well as other methods of investigation is of quite recent date. Thus some two years ago it was found by Arkwright that in pure cultures of dysentery, typhoid, and paratyphoid bacilli, two forms can be distinguished by the roughness or smoothness of their colonies, and that these forms also present some differences in antigenic respects. He notes that on subculture the attenuated strain may either revert to the other or remain unchanged. In a paper issued with the same report Dr. Eastwood gives a sketch of the present somewhat slender knowledge of bacterial variation and boldly discusses its relation to the phenomenon of transmissible autoysis of Twort and D'Herelle. Whatever may be the ultimate verdict as regards the natural relationship of two processes so apparently distinct, this latest contribution to the study of bacterial variation cannot fail to promote interest in a subject of practical as well as academic importance.

"Aberrant Q.R.S. complexes in all derivations—cardiac mortality 62.9 per cent. in 14.2 months.  
 "Control series—cardiac mortality, 21.3 per cent. in 13.7 months.  
 "In cases where T negativity was added to the aberrant Q.R.S. complex the death rate is increased up to 86.7 per cent. in 12.7 months."

At the Royal Victoria Hospital, Belfast, we followed up the history of fifteen patients treated in hospital who showed a bundle-branch lesion, and found all were dead within twelve months. Of course, it must be understood that this is only a statistical return, and that there are some cases of bundle-branch lesion in which the patient seems to go along wonderfully well. Take, for example, a patient of one of us, aged 70, who has had this lesion for at least five years, and who during that period has successfully weathered an acute attack of pneumonia.

#### INVERSION OF "T" WAVE.

To consider next the alterations which occur in the T wave of the electro-cardiogram is to enter upon the discussion of a physical sign the complete meaning of which we cannot as yet determine. On the other hand, it is a physical sign which we are able to recognize without difficulty; and again, from a statistical point of view, Dr. Willius has given us figures which, we think, are of most exceptional value. In the ordinary electro-cardiogram the T wave, which synchronizes with the systole of the ventricle, is upright in the first and second leads. It may be well to explain that in the first lead the heart lies in the circuit between the right and left hands; while in the second lead the heart lies in the circuit between the right hand and the left leg. As stated above, it is taken that the T wave is always upright in the normal individual in these leads, whereas in the third lead, between the left hand and the left leg, its direction may be below the horizontal line—that is, T negativity is present, or, we may say, the T wave is inverted (Fig. 4). Dr. Willius has divided his cases into four groups, and we have used this classification for a number of the patients we have been able to follow up at the Royal Victoria Hospital, Belfast. We give in detail, similar to that in Dr. Willius's papers, our results, which appear to be very comparable to his, if we remember that all our patients were in hospital in bed, seriously ill, whereas, no doubt, many of those of Dr. Willius were of the ambulatory type. We make this reference on account of our high death rate. We give also Dr. Willius's figures, including those he took from a control series of cases which did not show T negativity, carefully selected to be as clinically similar as

possible to those which showed this electro-cardiographic change.

These figures show how remarkable in prognostic value is this T negativity or inversion of the T wave. Dr. Willius excludes the possible fallacy of the inversion being due to digitalis, so that his investigations confirm what has been always a very deep impression—namely, that the physical sign of permanent inversion of the T wave in leads I, II and III is of grave prognostic significance.

FIG. 2.—Lesion of the right branch of the A-V bundle.

sclerosis 2; syphilitic aortitis 3; angina pectoris 1; auricular fibrillation 1.

Of these cases 19 were traced: 2 (1 of syphilitic aortitis and 1 of mitral regurgitation) were still alive; the remaining 17 were dead, after periods varying from three years to one month. The average duration of life after the initial examination was 12 months. The mortality is 89.47 per cent.

FIG. 3.—Lesion of the left branch of the A-V bundle.

the initial examination was 9.7 months. The mortality is 81.2 per cent.

#### Inversion of "T" Wave in Leads I, II, and III.

Eleven cases—males 6, females 5.

Endocarditis with mitral stenosis 1; aortic and aortic regurgitation 1; myocarditis

Of these cases 9 were traced: 4 were still alive—namely, 1 case of mitral regurgitation, 1 of myocarditis, and 2 of auricular fibrillation; 5 were dead, after periods varying from 1 year to one year. The average duration of life after the first examination was 28.5 months. The mortality is 55.5 per cent. This group, of course, is very small in numbers for statistical purposes.

#### Inversion of "T" Wave in Leads II and III.

Twenty-two cases—males 15, females 7.

Clinical Diagnosis: Endocarditis—mitral regurgitation 1; mitral stenosis 9; aortic regurgitation 1; aortic mitral regurgitation 1; myocarditis 2; syphilitic aortitis 1; pericarditis 1.

Of these cases 17 were traced: 7 were still alive—namely, 1 from aortic regurgitation, 2 from mitral regurgitation, and 1 from myocarditis; 10 were dead, after periods varying from three years to one month. The average duration of life from the first examination was 10.1 months. The mortality is 58.5 per cent.

FIG. 4.—Inversion of the "T" wave in leads II and III.

<sup>1</sup> Third Report of the Joint Council of the Order of St. John of Jerusalem in England and the British Red Cross Society, from April 1st, 1922, to March 31st, 1923. 19, Berkeley Street, W.1.

1. *Salpingostomy*.—As the result of a mild inflammation the tubal ostium may be sealed up, without evidence of other gross changes in the tube. An artificial ostium can be formed by making a longitudinal incision in the tube, as near to the ovary as possible, and oversewing the cut edges with fine silk to prevent reunion.

2. *Drainage of Pus Tubes*.—In cases of pyosalpinx the plan has been tried of laying the tube open from end to end and leaving it open to drain. This is done instead of removing the tubes. From the point of view of pregnancy, the chances can at least be no worse, as the result of drainage, than they were before; theoretically, they may be better. But it remains a question whether a tube that has been a pus sac for some time can ever regain its function. Personally I should not be at all sanguine about it; but only time can determine whether the experiment is sometimes worth trying. It may be found that the result as regards pregnancy is nil, and that the damaged tubes remain a source of danger and ill health. It would be necessary, when laying open tubes for drainage, to make sure that the uterine ostium of the tube was patent.

3. *Restoration of an Occluded Uterine Ostium*.—Where the tube is not too badly damaged but its uterine end is imperious, attempts have been made to restore this channel. The method adopted has been to pass a long straight needle, threaded with several strands of catgut, along the tube, through the isthmus, into the uterine cavity, and then across through the isthmus of the opposite side into the other tube. Another plan is to open the fundus of the uterus from the front and pass the strands of catgut from the uterine cavity into the tubes. The wound in the uterus is then closed. These ingenious methods are, of course, experimental; and here, again, time alone will show whether they have any practical value. If only one case of pregnancy followed the operation it would be worth while persevering with the attempts, since the alternative to operation is a hopelessly incurable sterility.

### *Conservative Surgery of the Uterus.*

Perhaps the first warning that should be uttered in this connexion is against meddlesome surgery of the cervix. It is the fashion in some quarters to amputate the cervix for prolapse and procidentia. No doubt it happens occasionally that amputation is required for elongation of the vaginal portion of the cervix. In prolapse there is an appearance of elongation of this portion, and perhaps some operators have mistaken this for a true hypertrophy, and they have thus been led to do an amputation, with results that can only be regarded as very bad from a conservative point of view.

1. *Repair of a Torn Cervix*.—This is eminently a conservative and prophylactic measure. A deep bilateral tear of the cervix is unfavourable to conception, partly because it is nearly always associated with "erosion," and this in turn causes a muco-purulent discharge, which is noxious to spermatozoa. If pregnancy does occur it is very liable to end in a miscarriage. Repair of the torn cervix is favourable to pregnancy. It is also a sound prophylactic procedure, because such a cervix is in a highly favourable condition for the development of carcinoma.

2. *Uterine Fibroids: Preservation of the Uterus*.—There are many cases in which uterine fibroids can be treated by myomectomy instead of hysterectomy. Several factors must be considered when deciding between the two operations; but they may be summarized by saying that myomectomy should always be done when it is surgically possible in a woman of child-bearing age, provided that other conditions are favourable for child-bearing, and that the operation does not leave a battered and useless uterus. After the age of 40 to 45 myomectomy seldom has any practical value. Papers advocating the more frequent performance of myomectomy were read by Mr. Bonney and myself at the meeting of the Obstetrical and Gynaecological Section of the Royal Society of Medicine in October, 1922.

3. *Radium in Chronic Metritis*.—There are cases of chronic metritis that prove refractory to repeated curetting and to vaccine treatment, and it has been found necessary in the past to do a hysterectomy in order to overcome excessive losses or constant purulent discharge. In a woman under 40 one hesitates to resort to this extreme step, and an alternative plan is now offered by radium. A tube containing 110-115 mg. of radium is introduced into the uterus after a slight dilatation and left for twenty to twenty-four hours. Many good results have been reported. The treatment is not devoid of the risk of inducing permanent atrophy of the ovaries, in which case the functional results would be even worse than those following hysterectomy. But even where the ovaries

have been affected it has sometimes been found that this result is transient, and menstruation has been renewed after some months, showing that the ovarian activity has been restored. A course of repeated applications of x rays seems to have a more damaging effect upon the ovaries than a single application of radium.

4. *Preservation of Cervix in Hysterectomy for Benign Conditions*.—A reference has already been made to this. There are, of course, cases where the condition of the cervix necessitates a total hysterectomy. But I am convinced that when the cervix can safely be left the subtotal hysterectomy is a better operation; and this partly for the reason that the vagina is left unaltered and so is better adapted for the continuation of married life.

## THE AFTER-EFFECTS OF CERTAIN INDUSTRIAL INJURIES, AND THEIR TREATMENT BY X RAYS.\*

BY

REGINALD A. MORRELL, M.R.C.S., L.R.C.P.,

HONORARY RADIOLOGIST TO THE SHEFFIELD ROYAL HOSPITAL; CLINICAL LECTURER, THE UNIVERSITY OF SHEFFIELD.

CERTAIN forms of industrial injury often result in limitation of function owing to the formation of an excessive amount of fibrous tissue during the process of repair. Examples of such injuries are those involving the tendons of the wrist or fingers after either primary or secondary suture; extensive lacerated wounds or burns of muscle, and even the less serious condition of teno-synovitis. One has only to recall the usual course of treatment in such cases—namely, a prolonged period of after-treatment in the massage and electrical department—to realize that there is a serious economic factor involved, for during this period the patient is being paid compensation and too often the end-results are not at all satisfactory.

It is apparent, therefore, that any treatment which will shorten this period of convalescence and which may possibly improve the end-results deserves to be widely known and extensively practised. The object of this paper is to urge the claims of radiotherapy in such cases. I venture to assert that the final results of suitable x-ray treatment are better and more quickly obtained than by the older and more usual methods of massage, movement, and negative electrolysis, all of which I have practised and have definitely discarded.

Whilst fibrous tissue is necessary for the restoration of function, the formation of such tissue in excess of actual requirements leads to that limitation of function which is so often a marked feature of these cases. The difficulty would be solved if we could change this scar tissue into a supple vascular tissue which would not interfere with function. This, I believe, is what is done by radiotherapy. I find that it is by no means uncommon for these cases to be discharged within a period of two or three weeks from commencing treatment. The treatment is carried out on three days a week only—in other words, an average of nine attendances of thirty minutes each is the only tax on the man's time. The more recent the injury the more easily will the final result be obtained. But the term "recent" is purely relative. It would be more accurate to say that the less fully organized, the more vascular the tissue, the more satisfactory the results. One case has been selected for a detailed report as it is a typical example of limited function resulting from just such an accident—namely, limitation of movement following on tendon suture and persisting in spite of two months' treatment by massage and movement. It was finally converted into an almost perfect functional result by eight treatments in the x-ray department spread over a period of two and a half weeks.

The patient had an extensive cut of the second finger of the left hand extending round the front and side of the proximal interphalangeal joint and severing the flexor tendons. The tendons were sutured and the patient was submitted to after-treatment in the massage department for two months. At the end of this time the condition was as shown in Fig. 1, the movement being limited and the finger thickened and painful.

\*A paper read before the Yorkshire Branch of the British Medical Association, June 1st, 1923.

and went to 107, Piccadilly the following year. From its earliest days many prominent members of the medical profession have belonged to it. Andrew Clark was the largest subscriber amongst the original guarantors. Ernest Hart figures amongst such historic names of original work in the proceedings of the congress. The social side of the native, and the other for the most outstanding paper on the best practical methods of hospital treatment Two prizes of 10,000 francs each were offered, one for the committee, under the chairmanship of Dr. Damos Mera. work in the proceedings of the congress. The social side of the congress was a series of official receptions, dinners, luncheons, dances, and garden parties. Fireworks, illuminated displays at night, a cinematograph entertainment, an excursion into the interior at Humabo, a hunting expedition at Mossamedes, and visits to local factories and places of interest, including hospitals, contributed to make the delegates' life a very crowded one, and full of interest. Not only at Louanda was entertainment provided, but also at Novo Redondo, Lobito, Benguela, and Mossamedes, and two enjoyable days were spent at the beautiful island of San Tome. The next congress is fixed for the year 1927 at Dakar.

MANUSLEY HOSPITAL COURSES.

The second part of the sixth course of lectures and demonstrations for the Diploma in Psychological Medicine will open at the Maudsley Hospital on October 8th. Dr. Edward Maudsley will deliver eight lectures on morbid psychology, on Mondays at 2.30 and 4.30 p.m., beginning on October 8th. Dr. Bernard Hart will give eight lectures on the psychoneuroses on Mondays at 3.30 and 5.30 p.m., beginning on November 5th. Sir Frederick Mott will give six lectures on the pathology of mental diseases, including brain syphilis, its symptomatology and treatment, on Tuesdays at 4.30 p.m., beginning on November 6th. Dr. C. Hubert Bond will give eight lectures on the legal relationships of insanity and treatment on Tuesdays, October 8th, 16th, and 23rd, at 4.30 p.m., and on Thursdays, October 11th and 25th, at 4.30 p.m. Dr. F. C. Shrubsole will give eight lectures on the practical aspect of mental deficiency on Wednesdays at 2.30 p.m., beginning on October 10th, and on Tuesdays at the same hour, beginning on November 6th. Dr. W. C. Sullivan, medical superintendent, Broadmoor Asylum, will give six lectures on crime and insanity on Wednesdays at 4.30 p.m., beginning on October 10th, and on Thursdays at the same hour, beginning on November 8th. Dr. Maudsley will give six lectures in clinical psychiatry on Wednesdays at 2.30 p.m., beginning on November 7th. Sir Frederick Mott and Dr. F. L. Golla will give twelve clinical demonstrations in neurology on Thursdays at 2.30 p.m., beginning on October 11th; the first six demonstrations will be given by the former at Camberwell Infirmary, and the second six by the latter at the Hospital for Paralysis and Epilepsy, Maidstone Vale, on Thursdays at 2.30 p.m., beginning on November 22nd. The fee for the whole of Part II of the course is ten guineas; for a single series of lectures, two guineas. The Fellowship of Medicine (1), Wimpole Street, W.1) will collect fees from, and issue tickets to, medical men intending to take the course who are introduced by the Fellowship. All inquiries regarding lectures, etc., should be addressed to the Director of the Pathological Laboratory, Maudsley Hospital, Denmark Hill, S.E.5.

The Canadian Medical Association is arranging for a Lecture to be given once every three years. The first of these will be given next year at the annual meeting in Ottawa by Dr. John Stewart of Halifax. Dr. Stewart was one of Lister's house-surgeons in the early days in Edinburgh.

Dr. Alexander Bruce, C.B., C.M.G., who for the past ten years has been Director-in-Chief of the Wellcome Bureau of Scientific Research, London, will resign that position on October 31st. His successor is Dr. C. M. Wenyon, C.M.G., C.B.E.

kingdom," and he added "of the whole world."

and divisions, not only of this great city, but of the whole and know everything that passes in the different quarters, furnished with the greatest variety of hints and materials, again quoting the *Spectator* of April 9th, 1711, "I am convinced," "By this means," as a member once said, principle, well expressed in the Club's motto, "Societas acquaintance and friendship, was and is the guiding same meal at the same table in order to preserve mutual one another. Simplicity in all arrangements and the maintenance of a table d'hôte, at which members partook of the Savile was a happy family, wit, and entertainment. The kept, their conversation must have been on a high level as members of the Club, but, judging by the company they tell us little or nothing about their individual characters. The reminiscences, as revealed by the historian, Pryn, and other prominent members of the medical profession. The reminiscences, as revealed by the historian, Pryn, and other prominent members of the medical profession. The reminiscences, as revealed by the historian, Pryn, and other prominent members of the medical profession.

WEST AFRICAN CONGRESS OF TROPICAL MEDICINE.

The first Congress of Tropical Medicine in West Africa was held from July 16th to 23rd, 1923, at Louanda, by the invitation of the Government of Angola. Those who know West Africa, and the difficulties of finding accommodation for 120 guests in one town, will appreciate the magnitude of the task put upon Portuguese hospitality. But the hosts rose splendidly to the occasion. Each delegate realized that he was not only a welcome but an exceptionally favoured guest, and this hospitality was extended also to wives and children of the "congressists." The object of the congress was to discuss the ways and means of attacking the medical and sanitary problems, more particularly with regard to the native inhabitants, of the colonies represented. The first session was devoted to sanitary organization; the following five were given over to practical methods and treatment of the prevalent diseases; and at the remaining sessions communications were read on the results of scientific research. At the opening meeting the municipal council formally offered its welcome and its magnificent chamber, and at a later stage the High Commissioner of the Republic in Angola—General Mendes Ribeiro Norton de Matos—officially, and in his capacity of honorary president of the congress, opened the proceedings. Eighty-three communications were read and discussed, mainly interest being centred on sleeping sickness, tuberculosis, leprosy, schistosomiasis, and malaria. Other subjects included blood and intestinal protozoa, pathogenic fungi, climatology, and anthropology. Seventy-six delegates attended the meetings, representative of Angola, French West Africa, French Equatorial Africa, Portuguese India, Mozambique, Paris, the Union of South Africa, and Nigeria, and the London School of Tropical Medicine. At the final meeting resolutions dealing with international public health reports, sleeping sickness, tuberculosis, and other diseases were passed. A full report of

## Memoranda :

### MEDICAL, SURGICAL, OBSTETRICAL.

#### THE TREATMENT OF SPRUE.

THE clinical resemblance between coeliac disease and sprue has been noted by several observers. Dr. Spence, who was at the time working on the former disease at the Hospital for Sick Children, Great Ormond Street, was good enough to see a case of sprue with me, and suggested that the comparatively fat-free diet used in cases of coeliac disease might be tried. The results of this treatment have proved satisfactory.

#### DIET.

5 a.m.—Cup of weak tea, 1 round of dry toast.  
8 a.m.—1 oz. casein, 1 pint machine-skimmed milk, and 1/2 pint of tea (without sugar), 4 rounds of dry toast, and 1 oz. cheese.  
11 a.m.—1/2 pint machine-skimmed milk, 1/2 oz. casein.  
11.30 a.m.—Juice of one orange.  
12 noon.—1 pint liver soup, 2 oz. minced chicken, 2 rounds dry toast, 4 oz. junket, 4 oz. calves' foot jelly. (*Note*.—The junket is made with skimmed milk. Liver soup is made by simmering 1 lb. of fresh liver with two pints of water for two hours, and then grating the liver into the liquid.)  
4 p.m.—1 oz. casein, 1 pint skimmed milk (machine), 1/2 pint of weak tea (without sugar), 1 oz. cheese, 2 cream crackers.  
8 p.m.—1 pint machine-skimmed milk, 1 oz. casein, 4 oz. junket, 1 oz. calves' foot jelly.  
10 p.m.—Juice of one orange.

The notes of the cases are as follows:

*Case 1.*—A. B., when admitted on December 4th, 1922, was seriously ill with sprue. Diarrhoea had begun in October, 1919. This had continued with intervals of slight improvement till June, 1922, when he had to give up work and remain at home on account of weakness and diarrhoea. He was extremely emaciated, weighing only 7 st. 3 lb. He was anaemic, the tongue was red, raw, and there were numerous superficial ulcers on it, and on the buccal mucous membrane. The abdomen was distended and tympanitic, and the liver dullness was considerably diminished. The stools, of which he was passing three or four daily, mainly in the early morning, were bulky, frothy, foul, and pale in colour, and contained 43.7 per cent. of fat. Attacks of tetany were frequent, and prevented him from sleeping. On the diet he improved rapidly; the tetany disappeared within two weeks, and in three weeks the motions had become solid, light brown in colour, and one or two in twenty-four hours. In the first week he gained 2 1/2 lb., in the second week 2 1/2 lb., and then an average of about 6 lb. a week till on April 23rd, 1922, he weighed 12 st. 2 lb. His general condition is now excellent.

*Case 2.*—C. D., admitted on February 1st, 1923, had suffered from morning diarrhoea since August, 1920. His condition was similar to that of A. B., except that there was no tetany. The tongue was red, raw, and with several painful ulcers. The stools were typical of sprue. His weight was 8 st. 12 lb. When put on the diet he improved rapidly, and at the end of eight weeks weighed 12 st. 7 lb.

*Case 3.*—E. F., invalided out of the navy with sprue on November 31st, 1919, had had all sorts of treatment in various hospitals. When admitted he had ulcers on the tongue and buccal mucous membrane, tympanitic abdomen, diminished liver dullness, and large, pale, foul, frothy stools. On the diet he rapidly improved, put on 14 lb. in weight, and now writes that he is looking and feeling exceedingly well.

I am indebted to the Director-General of Medical Services, Ministry of Pensions, for permission to publish this note, and to Drs. J. G. Wilmore and A. G. Wilkinson for the care they took in supervising the treatment.

Visiting Physician, Ministry of Pensions  
Hospital, Orpington.

#### HYPERSENSITIVENESS TO QUININE.

THE following case seems worth recording on account of the extreme severity of the symptoms occasioned by so small a dose as three-eighths of a grain of quinine, and of the divergence of those symptoms from those usually described as resulting from cinchonism.

Mrs. C., a spare woman of neurotic type, aged 50 years, married, two children, came under my care in June last, for the first time, suffering from a mild attack of influenza. Her past history presented no feature of clinical importance with the exception, as I subsequently learned, of her intolerance of quinine. This was discovered sixteen years ago, but the symptoms then were slight and the account now obtainable too vague to be of any value. Twelve years ago she was given a tonic containing iron and quinine citrate, and after taking a few doses she became very ill, with vomiting, diarrhoea, and erythema of the lower extremities, which was

followed by desquamation. Three years ago she was given a mixture containing ammonia and 20 minim doses of compound tincture of cinchona. A few doses again produced gastro-intestinal disturbances, and intense erythema of the lower extremities extending as high up as the iliac crests. In from twenty-four to forty-eight hours the skin in this region presented a mottled purple appearance such as that of extensive ecchymosis, and later underwent dry desquamation. There was also a slighter and more patchy affection of the arms.

Unaware of these details, during her convalescence in June I prescribed for the patient iron and quinine citrate in 5-grain doses. She thought she recognized the mixture as similar in appearance to that which caused the trouble before, and therefore took only half a dose, which represents three-eighths of a grain of quinine. This was followed almost immediately by faintness and giddiness. She took brandy and went to bed. Within an hour she began to complain of a burning sensation in the upper abdomen accompanied by vomiting and diarrhoea which lasted for twenty-four hours. There was severe irritation of the lower extremities, the itching of which she described as intolerable. Within a few hours the legs became deep red up as high as the iliac crests, at which level the erythema definitely ceased. The hands and forearms were affected somewhat later and in a lesser degree. After twenty-four hours the erythema gave place to vesiculation; the entire surface of the thighs and buttocks presented, in fact, the appearance of a burn of the second degree. The legs, feet, and affected parts of the upper extremities did not vesiculate, but after a few days underwent desquamation. The temperature varied between 99° and 101° F. For treatment, calcium lactate was given by mouth and the skin lesion was treated as if it were a burn. The condition cleared up in about fourteen days.

It is noteworthy that with each attack the susceptibility to the drug has increased and lasted in spite of one interval of nine years; also that there has been on each occasion the same definite demarcation between the affected and the healthy skin areas.

Rye, Sussex.

FRANCES E. BELL, M.B., B.Ch.

#### A "PRIVY" BIRTH.

THE following notes of a "privy" birth seem to be of value, especially from a medico-legal point of view.

About 3.15 a.m. on May 13th last I was called up to visit a woman who lived about two miles out in the country. I arrived at 3.45, and was met at the door by a neighbour of the woman, who was in a state of great trepidation. She stated that "something had happened" in the closet, but that she was too frightened to go and see what had happened. Finding that the woman was then in bed and apparently fairly well I went at once to the closet, about fifty yards away. This turned out to be a small open privy of a most primitive type, with two side walls, a back wall, a galvanized sheet of iron for roof, but with no door. On looking into the privy I saw the face of a child about half a yard below the level of the seat, the rest of the body being embedded in the contents of the pit. The child made a feeble inspiratory effort. I lifted the body out with cord and placenta attached, and carried it into the house. When nearing the house I noticed another slight inspiratory effort. The child was mature, pulseless as far as I could ascertain, stone cold, and with the appearance of a cadaver. The birth had taken place a full two hours before my visit. The ground around was covered with a hoar frost at the time. After a hurried removal of some of the filth the child was wrapped in warm flannel and artificial respiration started. I had two women assistants; one I instructed to massage the feet, the other to apply friction to the vertex. After about fifteen minutes of this four or five regular spontaneous respiratory movements were made, followed by an interval before they were again resumed. This continued for a considerable time, and it was not until an hour had passed that they became definitely continuous. The child was then put into a warm bath; the body was still cold when taken out of this, but breathing was regular and the child did well, and is well at the present date.

When doing artificial respiration I made gentle pressure and release movements over the epigastrium, which I had found effectual in other cases of resuscitation of the newborn. It was noticeable that, if the woman who was applying friction to the vertex stopped doing so during the time that regular respiration was being established, an arrest of the respiratory movements at once occurred. This seemed to give a valuable reflex stimulus.

The following points seem notable: (1) the child was in the privy for two hours; (2) the privy was an open one and the outside temperature below freezing point; (3) the cord and placenta were attached; (4) the child was dying when I arrived, was pulseless and stone cold; (5) resuscitation occupied one hour.

Lionsauffraid, Montgomey.

W. H. LEWIS, M.B., B.Sc.

*The Electron and the Proton.*

We know that the electron has a negative charge of one fundamental unit, while the charged hydrogen atom, whether in electrolysis or in the electric discharge, has a charge of one positive unit. But the mass of the electron is only  $1/1836$  of the mass of the hydrogen atom; no evidence has been found of the existence of a positive electron of small mass like the negative. In no case has a positive charge been found associated with a mass less than that of a charged atom of hydrogen. The small mass of the negative electron is to be associated with the energy of its electrical minimum, so that the electron may be regarded as a disembodied atom of negative electricity. The hydrogen atom is the lightest of all atoms, and is presumably the simplest in structure, and the charged hydrogen atom, which is to be regarded as the hydrogen nucleus, carries a unit positive charge. It is thus natural to suppose that the hydrogen nucleus is the atom of positive electricity, or positive electron, analogous to the negative electron, but differing from it in mass. There is the strongest evidence that the atoms of matter are built up of these two electrical units—namely, the electron and the hydrogen nucleus or proton, as it is usually called when it forms part of the structure of any atom. It is probable that these two are the fundamental and indivisible units which build up our universe.

*The Nuclear Atom.*

Professor Rutherford described the conception of the nuclear atom according to which the heart of the atom consists of a minute but massive nucleus, carrying a positive charge of electricity and surrounded at a distance by the requisite number of electrons to form a neutral atom. In a heavy atom like that of gold the radius of the nucleus, if supposed to be spherical, is less than one-thousandth of the radius of the complete atom surrounded by its electrons. These outer electrons are in some way held in equilibrium by the attractive forces of the nucleus, and their arrangement and motion must be governed entirely by the magnitude of the nuclear charge. Since the ordinary chemical and physical properties are to be ascribed mainly to the configuration and motion of the outer electrons, it follows that the properties of an atom are defined by a whole number representing its nuclear charge.

*Moseley's Law and Bohr's Theory.*

Professor Rutherford went on to explain Moseley's law, which fixed the number of electrons in all the atoms, and showed that the properties of an atom are determined not by its atomic weight but by its nuclear charge. He dealt briefly with the quantum theory, and sketched the method by which Bohr has sought to determine the distribution of the electrons around the nucleus of any atom and to fix the quantum numbers that characterize the motion of each electron, and to form a rough idea of the character of the orbit.

The first element, hydrogen, he continued, has a nuclear charge of 1 and 1 electron; the second, helium, has a charge of 2 and 2 electrons, moving in coupled orbits. These two electrons form a definite group, known as the K group, which is common to all the elements except hydrogen. For increasing nuclear charge the K group of electrons retains their characteristics, but move with increasing speed, and approach closer to the nucleus. As we pass from helium of atomic number 2 to neon, number 10, a new group of electrons is added consisting of two subgroups, each of four electrons, together called the L group. This L group appears in all atoms of higher atomic number, and, as in the case of the K group, the speed of motion of the electrons increases, and the size of their orbits diminishes with the atomic number. When once the L group has been completed a new and still more complicated group of electrons begins forming outside it, and a similar process goes on until uranium, which has the highest atomic number, is reached.

*A Visualization of the Planetary System of the Atom.*  
It may be of interest to try to visualize the conception of the atom we have so far reached by taking for illustration the heaviest atom, uranium. At the centre of the atom is a minute nucleus surrounded by a swirling group of 92 electrons.

*Chemical Combination.*

So far no reference has been made to the very difficult question of the explanation on this theory of the chemical combination of atoms. In fact, as yet the theory has hardly commenced itself with molecular structure. On the chemical side, however, certain advances have already been made, notably by G. N. Lewis, Kossel, and Langmuir, in the interpretation of the chemical evidence by the idea of shared electrons, which play a part in the electronic structure of two combined atoms. There can be little doubt that the next decade will see an immense attack by physicists and chemists on this very important but undoubtedly very complicated question.

*The Nucleus of the Atom.*

The nucleus of the atom is still a comparatively unexplored territory, though the study of radio-active bodies has provided us with very valuable information on the structure of the nucleus, for we know that the  $\alpha$  and  $\beta$  particles must be expelled from it, and there is strong evidence that the very penetrating  $\gamma$  rays represent modes of vibration of the electrons contained in its structure. In the long series of transformations which occur in the uranium atom, eight particles are emitted and six electrons, and it seems clear that the nucleus of a heavy atom is built up, in part at least, of helium nuclei and electrons. It is natural to suppose that many of the ordinary stable atoms are constituted in a similar way. It is a matter of remark that no indication has been obtained that the lightest nucleus—namely, that of hydrogen—is liberated in these transformations, where the processes occurring are of so fundamental a character. At the same time, it is evident that the hydrogen nucleus must be a unit in the structure of some atoms, and this has been confirmed by direct experiment. Dr. Chadwick and I have observed that swift hydrogen nuclei are released from the elements beryllium, nitrogen, sodium, aluminium, and phosphorus when they are bombarded by swift  $\alpha$  particles, and there is little room for doubt that these hydrogen nuclei form an essential part of the nuclear structure. Professor Rutherford then gave a short account of the theory of "isotopes," which, he said, strongly supported

gold curve was obtained in 50 per cent., and the luctic type of curve in about 16 per cent. of the cases. Arsenical treatment is stated to be the most successful method, and the use of neo-salvarsan and mercury is mentioned, but without any enthusiasm. There is a copious bibliography, which adds to the value of this book as a useful source of reference.

## TWO FRENCH TEXTBOOKS OF PSYCHIATRY.

THE sixth edition of Dr. J. ROGUES DE FURSAC's well known *Manuel de Psychiatrie*<sup>3</sup> contains much new material. He points out that the last few years have furnished mental pathology with a number of facts of considerable practical and theoretical interest. Amongst these he refers to the harvest of clinical data which has resulted from the discovery of lethargic encephalitis. Actually, the account he gives of this disorder is scarcely adequate in view of its importance to psychiatry, and only eight lines are devoted to encephalitis in children. Recent developments in the treatment of general paralysis are discussed at length. The author regards the results of antisyphilitic treatment as distinctly encouraging, and his own experience has led him to the view that the most severe symptoms can be alleviated by active therapy. He regards Von Wager's methods of treatment also as promising, and has personally observed remarkable improvement in general paralysis after infective fevers. The section dealing with constitutional psychopathic states (hypermotivity, psychasthenia, obsessions, hypochondriasis, etc.) has been considerably augmented, and includes, rather unfortunately we feel, under the same category the congenital group, idiots, and imbeciles. On the whole, the French school of psychiatry would appear to stress unduly the constitutional factor in the various forms of inadequacy. There must be very few people, indeed, who are not subject to episodes of anxiety, feelings of inferiority, mild obsessions, and so on, as a result of other than constitutional factors. The ability to cure and overcome such psychoneurotic symptoms probably depends largely on the degree of constitutional weakness, a fact which was revealed in a striking manner in the war psychoneuroses. Dr. de Fursac is specially interested in the problems of medico-legal psychiatry, and a section is devoted to this subject. The book is comprehensive, and the additional material has brought it thoroughly up to date. We have no doubt it will continue to maintain its position as one of the leading French textbooks of psychiatry.

*Psychiatrie du Médecin Praticien*<sup>4</sup> is one of a series of volumes intended for the use of the general practitioner rather than the specialist. The initial difficulty experienced by the practitioner in dealing with mental cases is to place them into categories which carry with them some notions as to causation, development, and prognosis. Diagnosis is much more difficult in the psychoses than in physical diseases, where the symptoms can usually be referred to some special organ or system. Recognizing this, the authors of the book before us, Drs. M. DIDE and P. GUIRAUD, have sought to furnish clear clinical descriptions of the various forms of mental disorder in order that the practitioner may be in a position to recognize the category to which a case belongs. A number of excellent plates depicting the main clinical types are included in the volume, and serve to illustrate and vitalize the written descriptions. The opening chapter deals with the subject of unconscious mentation, but in the sections which follow the authors confine themselves to a descriptive rather than an interpretative account of their cases, and they do not appear to have been influenced to any notable extent by Freudian theories. The book is excellently printed and the arrangement of headings and paragraphs renders it clear and readable. The French practitioner should find the volume useful and suited to his needs. It will also give the English psychiatrist a good general outline of French psychiatry, though it cannot be said to include any new facts or theories of interest to the specialist.

<sup>3</sup> *Manuel de Psychiatrie*. By J. Rogues de Fursac. Sixth edition revised and augmented. Paris: Félix Alcan. 1923. (Cr. 8vo, pp. xvi + 906; 4 plates. Fr. 30.)

<sup>4</sup> *Psychiatrie du Médecin Praticien*. By M. Dide and P. Guiraud. Paris: Masson et Cie. 1922. (Cr. 8vo, pp. 415; 8 plates. Fr. 20 net.)

## PEDIATRICS.

WE are not surprised to learn from the preface to the second edition of Dr. H. C. CAMERON's excellent little book on *The Nervous Child*<sup>5</sup> that some have found fault with the title, maintaining that the book should have been called, not "The Nervous Child," but "The Normal Child," presumably on the ground that the manifestations with which the author deals are found in all normal children. Perhaps such a title as "The Mental Hygiene of Childhood" would have been best, though it might not have been so attractive as that actually chosen. The keynote of the book is to be found in the concluding lines—"The hygiene of the child's mind is as important as the hygiene of his body; both are studies proper for the doctor." The present edition contains a new chapter on management and conduct, in which the author, while acknowledging the value of Freud's contribution to psychology, deprecates the indiscriminate application of his teaching to abnormal conduct in children, and by several striking examples shows how these faults may be due to mismanagement by parents or nurses. Timidity, anxiety, and fears are particularly apt to develop in the children of very devoted parents, especially in the only child, on whom all the care is concentrated. Again, bad temper, disobedience, and negativism are most likely to arise as the result of an unrestful atmosphere in the home in response to attempts at control which are at once ineffectual and persistent. We can cordially recommend this work to the family practitioner and to all interested in the management of children.

The ninth edition of Dr. LOUIS FISCHER's textbook on *Diseases of Infancy and Childhood*,<sup>6</sup> the first edition of which was published in 1907, differs from the previous issues in that it is divided into two volumes. The first volume is in six parts, devoted respectively to infant feeding, the development and hygiene of the infant, diseases of the newborn, alimentary diseases, diseases of the heart, liver, spleen, pancreas, peritoneum, and genito-urinary tract, and diseases of the respiratory system. The second volume also consists of six parts, which deal with infectious diseases, diseases of the blood and ductless glands, nervous diseases, diseases of the ear, eye, skin, and abnormal growths, diseases of the spine and joints, and miscellaneous subjects, including developmental exercises, anaesthesia, disinfection, and administration of drugs. Numerous changes have been made in the text and additions to the illustrations, which, as we pointed out in our notice of a previous edition (BRITISH MEDICAL JOURNAL, March 22nd, 1913, p. 617), are of great value. Special attention has been given to the home modification of milk; the chapter on vitamins has been rewritten, and those on the diagnostic and therapeutic value of x rays and the diagnostic importance of lumbar puncture revised. A chapter on transfusion has been added. The work, which is provided with an index in each volume, will prove a useful addition to the practitioner's library.

## PRACTICAL PHYSIOLOGY.

*Practical Physiology*,<sup>7</sup> by ANREP and HARRIS, is a laboratory manual, not intended for self-tuition, but for use under the guidance of qualified teachers. In planning the book no account has been taken of examination requirements; some of the exercises given could be set at a practical examination, while others, much more important, would be inappropriate. It embraces the work suitable for junior and senior medical students and advanced students of physiology.

In making their selection of laboratory experiments the authors have aimed at striking a balance between the

<sup>5</sup> *The Nervous Child*. By Hector Charles Cameron, M.A., M.D., F.R.C.P. Second edition. London: Henry Frowde, and Hodder and Stoughton. Oxford Medical Publications. (Cr. 8vo, pp. vii + 224. 7s. 6d. net.)

<sup>6</sup> *Diseases of Infancy and Childhood: Their Dietetic, Hygienic, and Medical Treatment: A Textbook Designed for Practitioners and Students of Medicine*. By Louis Fischer, M.D. Ninth revised edition; 2 volumes. Philadelphia: F. A. Davis Company. 1922. (Med. 8vo. Vol. I, pp. xxvii + 603; 146 figures, 37 plates. Vol. II, pp. ix + 605; 247 figures, 43 plates. 12 dollars the 2 volumes.)

<sup>7</sup> *Practical Physiology*. By G. V. Anrep, M.D., D.Sc., and D. T. Harris, M.B., B.Sc. Introduction by Professor E. H. Starling, O.M.G., M.D., F.R.C.P., F.R.S. London: J. and A. Churchill. 1923. (Roy. 8vo, pp. x + 212; 197 figures. 10s. 6d. net.)

## INDIGENOUS SYSTEMS OF MEDICINE IN

## INDIA.

AYURVEDA, SIDDHA, UNANI.

On February 21st, 1921, the Madras Legislative Council passed a resolution recommending the Government to take early steps to encourage the indigenous systems of medicine. Under G.O. No. 1351, P.H., Press, dated October 17th, 1921, the Government appointed a committee to report on the question of the recognition and encouragement of indigenous systems of medicine in vogue in the Presidency. The object of the Government in ordering the inquiry was to afford the opportunity to state their case fully for scientific criticism, and to justify State encouragement of these systems. With this end in view a questionnaire was prepared and sent round to all persons interested in this matter. No less than 122 replies were received from all parts of India, including Indian States. Further, forty representative witnesses were visited and conferred with the leading exponents of medicine and important centres of the indigenous systems of medicine and other persons interested in their promotion. On February 17th, 1922, the committee presented its report, consisting of 150 pages, of which nearly one hundred are devoted to a description of the indigenous systems. Much of the remaining portion of the report has reference to such practical matters as registration, the organization of medical education, and finance; questions of this nature appear to be outside the scope of the inquiry, and need no comment.

## Statistics.

For a population of more than 42,500,000 inhabiting the Madras Presidency, the total number of practitioners following the European system is not more than 3,000; the number following the Indian systems is reckoned at 21,000 by the committee and at about 4,000 by the local authorities. Commenting on the discrepancy between the last two figures the committee states that "apparently the standard of our local authorities in judging our Ayurvedic and Unani practitioners is very high, otherwise we would not have 'a belief that there is hardly a village, especially in the south, without its own vaidyas or hakims.' These, however, do not apparently count in the judgement of our local authorities."

The point is one of importance because the main object of the inquiry was to ascertain the value of the Indian systems as seen in present-day practice, and not merely in its historical aspect which figures so largely in the report. If four-fifths of the native practitioners are considered to fall below a certain unimpaired standard, it is desirable to know what degree of medical erudition they possess. If it is true that Ayurveda has practically died out among the people, why the modern European system should not be introduced in place of the ancient one, if it is superior to the latter. The report furnishes very little information in this connection, but scattered references lend support to the view that the local authorities were not actuated entirely by prejudice. Thus:

"It would be self-deception on our part to think that we sit on a high pedestal. The fact is unfortunately the other way. The intellect saw the principle and rough-hewed the discovery, but invention was sometimes belittled in comparison with discovery, but invention was the potential birth of discovery. The intellect saw the principle and rough-hewed the discovery. The exhibition was then inspected. Special interest was shown in the demonstration by Dr. A. O. Rankine, professor of physics in the Imperial College of Science, South Kensington, of an instrument by which sounds of transmitted light, and the fluctuations of the beam are reproduced as sound at the receiving station. In the demonstration at Liverpool the space covered was about 200 yards, but as long a distance as a mile and a half has been traversed. The distance appears to be limited only by the curvature of the earth, and Professor Rankine suggested especially in synchronizing speech with the picture in cinematography."

"Can it be denied that the art has at present decayed to such an extent that it is not equal to the task of ministering to the surgical needs of our teeming millions?"

"Even assuming for a moment that such branches of Indian medicine as surgery and midwifery were not merely the forgotten arts that they are now . . ."

"Can it be denied that the art has at present decayed to such an extent that it is not equal to the task of ministering to the surgical needs of our teeming millions?"

"Even assuming for a moment that such branches of Indian medicine as surgery and midwifery were not merely the forgotten arts that they are now . . ."

## Exhibition.

Following the example of the British Medical Association and some other associations which hold annual meetings, the British Association has this year, for the first time, arranged an exhibition of scientific appliances, illustrating the apparatus used in research laboratories in the industrial application of scientific investigations. It is displayed in the Central Technical School. The exhibition was opened by Sir Charles Sherrington, President of the Royal Society and retiring President of the British Association, on the afternoon of September 10th. In a short address he said that instruments used in the service of natural science were becoming inevitably far more complex. The connection between the tool and the man was so close that it was difficult at times to unravel the share the scientific tool had in the process. Though discovery was not synonymous with invention the connection between the two was very close. The proverb said that necessity was the mother of invention, but it might be truer that curiosity was the mother of invention, for apparatus had come into existence to satisfy what might be called the divine curiosity of man, who was not satisfied with understanding only the appearances of things. Invention was sometimes belittled in comparison with discovery, but invention was the potential birth of discovery. The intellect saw the principle and rough-hewed the discovery. The exhibition was then inspected. Special interest was shown in the demonstration by Dr. A. O. Rankine, professor of physics in the Imperial College of Science, South Kensington, of an instrument by which sounds of transmitted light, and the fluctuations of the beam are reproduced as sound at the receiving station. In the demonstration at Liverpool the space covered was about 200 yards, but as long a distance as a mile and a half has been traversed. The distance appears to be limited only by the curvature of the earth, and Professor Rankine suggested especially in synchronizing speech with the picture in cinematography."

In order to obtain the best results certain conditions must, however, be fulfilled. It is necessary that our universities and other specific institutions should be liberally supported, so as not only to be in a position to train adequately young investigators of promise, but also to serve themselves as active centres of research. At the same time there must be a reasonable competence for those who have shown a capacity for original investigation. Not least, progress in many directions the co-operation of nations is as essential as the co-operation of individuals. Science, no less than industry, desires a stability not yet achieved in world conditions.

There is an error far too prevalent to-day that science progresses by the demolition of former well established theories. Such is very rarely the case. For example, it is often stated that Einstein's general theory of relativity has overthrown the work of Newton on gravitation. No statement could be farther from the truth. Their works, in fact, are hardly comparable, for they deal with different fields of thought. So far as the work of Einstein is relevant to that of Newton, it is simply a generalization and broadening of its basis; in fact, a typical case of mathematical and physical development. In general, a great principle is not discarded but so modified that it rests on a broader and more stable basis.

It is clear that the splendid period of scientific activity which we have reviewed to-night owes much of its success and intellectual appeal to the labours of those great men in the past, who wisely laid the sure foundations on which the scientific worker builds to-day, or to quote from the words inscribed in the dome of the National Gallery, "The works of those who have stood the test of ages have a claim to that respect and veneration to which no modern can pretend."

In his book on the Villemin military hospital during the war<sup>12</sup> Professor FÉLIX LEJARS, who succeeded the late Professor Gaucher as officer-in-charge, has given an interesting account of the valuable work performed during the war in a Paris hospital which, though it had been condemned as out of date for over thirty years, possessed the great advantage of being near two important railway stations serving the front. In addition to instructive statistics relating to gunshot wounds, gas gangrene, amputations, tetanus, antityphoid inoculation, and influenza, the volume contains a vivid description of the difficulties attending the administration of such an antiquated hospital as well as of the important events in the life of the hospital during the war, such as the visits of Clémenceau during the bombardment by "Big Bertha," the decoration of dying men, the funeral of Gaucher, and the celebration of armistice day. The book, which is written in a mildly satirical vein, will particularly appeal to those surgeons who, like Professor Lejars, suddenly found themselves during the war placed in charge of a military hospital without any previous military training.

The second volume of Richter's *Organic Chemistry* dealt only with the class of substances termed carbocyclic, or those formed from ring nuclei containing no atom but carbon in the ring. The third volume<sup>13</sup> now issued treats of the heterocyclic compounds of organic chemistry, or ring compounds of carbon in the formation of which atoms of the inorganic elements participate. These comprise the furane and thiophene derivatives; the indole group, under which heading are given the various syntheses of indigo which have been accomplished; the pyrazolines, of which antipyrin is a member; the pyrones, which include the meconic acid of opium; and also the pyridine and quinoline series, among the members of which are found most of the important alkaloids. The composition and style of compilation are as in the preceding volumes, leaded type being used for the names of substances under description and italics for those coming incidentally under reference. Condensation continues to be a conspicuous feature of the work: it is the inevitable result of an endeavour to mention every substance registered in original treatises. But the drawback resulting from condensation is repaired very well, first by the arrangement, and secondly by the skill shown in selecting for mention the most salient facts. When tested by referring to specific subjects it is found that nothing of outstanding importance is omitted. The whole is very completely indexed. No book could be more desirable for general reference on the chemical constitution and relationships of organic materials.

In a popular Sunday afternoon lecture at the Harvard Medical School, which formed one of the series of the Harvard Health Talks, Dr. F. T. LORD, physician to the Massachusetts General Hospital, gives in clear language a thoroughly up-to-date account of *Pneumonia*,<sup>14</sup> which in the United States of America is responsible for 10 per cent. of all deaths, and was therefore called by the late Sir William Osler "the captain of the men of death," the phrase applied by John Bunyan to pulmonary tuberculosis. This lecture gives a description of the types of pneumococci, Types I, II, and III being the fixed types, and Type IV a heterogeneous group; Types I and II are rarely present in the normal mouth, whereas Types III and IV are common, more than 50 per cent. of healthy persons having some kind of pneumococcus in their mouths. Sixty per cent. of the cases of lobar pneumonia are due to pneumococcus Types I and II, and as these organisms are rarely normal inhabitants of the mouth the disease is due to infection, whereas the 40 per cent. of pneumonic cases due to Types III and IV may be regarded as due to auto-infection under conditions of increased virulence. About a third of the cases of pneumonia Types I and II prove fatal, nearly a half of Type III, and only one-eighth of the cases of Type IV pneumonia. The mechanism of the crisis in lobar pneumonia is explained as due partly to a progressive rise in the general resistance to the pneumococcus, and partly to a local increase in the acidity of the lung whereby the acid death point of the sensitive pneumococcus is reached. In bronchopneumonia Types III and IV are more common than the other two. The prevention of pneumonia by various precautions and also by inoculation

with a pneumococcus vaccine is described, and an account of the treatment both by general measures and by the Type I pneumococcus serum is given. Although intended for lay hearers, the lecture provides medical men with a short and useful summary of the most modern conception of the pneumonia question.

## FACTORY HYGIENE.

### ANNUAL REPORT OF THE CHIEF INSPECTOR.

It is becoming increasingly noticeable with each successive year of publication of the Annual Report of the Chief Inspector of Factories how much the work of the Department is altering in its character and scope. The introduction of scientific medical investigation into the factory, a great forward movement in itself, has brought to light so many definite causes of ill health that experts of various kinds have had to be extensively requisitioned to devise methods and means for affording the necessary protection for the workers. The filip given during war time to the intensive study of the physiology and pathology of fatigue and of the human factor in accident causation has had its influence in the production of welfare schemes and "safety first" movements, and the rapid progress made by electricity as a motive power quite recently brought about the necessity for creating a special section of the inspectorate. It is, therefore, not surprising that Mr. G. Bellhouse, in this his first report (for the year 1922)<sup>1</sup> as Chief Inspector, should make a point of explaining that his object is to give a general picture of the work of his department and to enlarge more particularly upon subjects that have been occupying the special attention of his staff. This he has done very satisfactorily.

The low ebb at which trade conditions have remained has apparently accounted for the marked decrease in routine work, but *pari passu* this circumstance appears to have provided not only more time and opportunity for special investigations by the department but has been taken advantage of by firms to modernize their plants and improve their methods against the turn of the tide, distinct signs of which are said to be in evidence.

Some indication of the extent of trade depression is provided by comparing the numbers of examinations during the year for certificates of fitness, 267,964, with the pre-war figure of 529,491 for 1913. Medical examinations under special rules and regulations were 212,195, as against 175,735 for 1921 and 225,678 for 1920; the number of accidents was 97,986 (including 843 fatal), an increase of 5,421 over the previous year. It does not appear likely that any of these figures have been materially affected by the formation of the Irish Free State.

In dealing with the safety problem mention is made of the attention again devoted to trade agreements respecting fencing and precautions, and there is an excellent section describing the risks of bursting of revolving discs, wheels, and centrifuges due to centrifugal stress. Under the heading of dangerous trades it is stated that twenty-nine codes of regulations were in force at the end of the year, the recent ones being those for aerated water, hides and skins, celluloid, india-rubber, and chemical works. There is the usual chapter on the dangers from electricity and two special chapters by the senior engineering inspector, one of the latter dealing with the risks arising during repairs to oil-carrying ships.

The work of the medical section is, as usual, described by Dr. T. M. Legge, but in addition there are two special reports, one by Dr. E. L. Middleton and the other by Dr. Eileen Hewitt. Dr. Legge gives his usual table showing the number of notifications of industrial poisoning, epithelioma, and anthrax during the year, and comparing these with the yearly incidence since 1900.

### Lead Poisoning.

The lead cases were 247, with 26 deaths, as compared with 1,058, with 38 deaths, in 1900. The pottery trade heads the list with 42 cases and 17 deaths; the accumulator industry provides 32, with no deaths; plumbing and soldering

## THE HEALTH HISTORY OF MANCHESTER.

On his retirement after nearly thirty years' work as medical officer for Manchester, Dr. James Niven has put the city permanently in his debt by writing a history of its public health.<sup>1</sup> Locally the volume will be invaluable, not only for its careful and detailed account of the work of the health authorities in Dr. Niven's time and that of his predecessors, but also for his frank and shrewd observations made on the methods of local government, and for advice as to the future. These parts of the history will be of special interest and profit to his colleagues throughout the public health service of Britain. The book is a plain, straightforward story, entirely free from rhetoric. The title of the first section is "Forms of Dirt," whilst the smoke nuisance is dealt with under a heading consisting of the single word "Blacks." In the first paragraph of his introduction Dr. Niven plunges at once in *medias res*, and regrets that he has not been able to exterminate the elusive house fly, with its large responsibility for summer diarrhoea. Generous appreciation of the work of his assistants and colleagues is a feature of his writing, especially perhaps as to the aid which he received from the late Professor Delépine, who conducted many valuable laboratory investigations. That Dr. Niven kept himself always up to date in his acquaintance with the progress of scientific research on matters in his own sphere has helped to make him a wise and safe guide in the health administration of one of the great cities of the empire.

After his initial discourse on the influence of dirt, he goes on to write about Manchester's hospitals and sanatoriums, its infectious diseases, devoting separate sections to venereal diseases and tuberculosis; then he proceeds to milk, foodstuffs, and food poisoning, including an account of the great outbreak of arsenical poisoning in beer drinkers at the beginning of the present century. He next takes up the history of housing in Manchester, and maternity and child welfare, and concludes (apart from some observations on statistics) with an important section on the evolution and present constitution of the Public Health Department.

Within the limits of this article it is impossible to follow the volume through all its sections, but everything about housing is of special present interest. Dr. Niven says:

Manchester is a city of cottage dwellings, the prevailing type being the four, five, or six-roomed house. Houses therefore cover a large area in proportion to the number of persons to an acre, as the tenement dwelling has found no acceptance and no home outside the centre of this city. One effect of this is an aspect of dreary monotony.

It is well to remember, therefore, that even cottage dwellings may be monotonous, and to take note of this in new building schemes. Ultimately, of course, there comes the rival claim of convenient nearness and accessibility to daily work, to be met so far by travelling facilities. Manchester's first building by-laws were in 1868, and did not require even damp-proof courses, but insisted on a minimum street width of thirty feet. Even these by-laws were of some use, while those of 1890 and 1908 were better, but the latter were passed just before the building slump. In the older parts of the city back-to-back houses abounded, usually of two apartments, with filthy privies standing in stacks in courts or at street ends. Various areas were dealt with under the Housing Acts, and ground was bought for buildings, but an experiment of a five-story tenement was a failure and not repeated, two stories being much more acceptable. The problem of the 10,000 back-to-back houses was tackled, and vast improvement effected. So the story of constant effort goes on, and Dr. Niven records that an immense result has been achieved, though over considerable areas houses are deteriorating, and ought to go "not one by one but in areas." In Manchester, however, as elsewhere, "private building of cottages appears for the time to have been extinguished, and the State has accepted the obligation," but State-aided houses are up till now few in number, and almost

restricted to discharged service men, so that the general body of the people are little better off than before, and if the new houses were there "most persons could not pay the rents." How, then, is the situation to be met? In answer to that question Dr. Niven asks another: "Can we not resolve to follow the example of America and go dry? Can there be any doubt that the liquor trade paralyses the hands of the social reformer and keeps the people poor?"

Of all the great cities of Britain Manchester can less than any other be regarded as a unit independent of its neighbours. If a man goes outside of Glasgow he may straight away find himself at the Kyles of Bute, or on Lochlomondside, or in Strathendrick; if out of Edinburgh he is into the Scott country or at Dunbar or Gullane. But if he gets out of Manchester it is only to transfer himself to Salford or Bolton or Oldham. And so, even in housing reform Manchester could act only very incompletely by itself, and Dr. Niven justly congratulates himself that over a hundred sanitary authorities within fifteen miles of Manchester have joined with it to make their town-planning arrangements and main roads and transport fit into one another.

Dr. Niven's volume shows throughout that he has not confined his work within narrow or official limits. He has been in co-operation with the social activities of Manchester, as with a guild established by ladies in 1908 to assist mothers in various ways, by lessons in hygiene, sewing, cookery, and medical consultation centres. Valuable service was rendered in feeding mothers and children in the distressed period 1915-16, and subsequently under an order of the Local Government Board, but questions arose as to such relief being given where not justified, and on investigation the system had to be changed. Even yet "it is no easy matter to be sure that public money is properly expended," and in a passage which illustrates Dr. Niven's strong common sense he writes:

"It is a pity that the work of the centres should be inwoven with a scheme for the sale of milk under cost, as it makes it difficult to determine when an advance in the popularity of the centres is due to appreciation or to material aid. Such aid should, as far as possible, be confined to periods of distress. In my opinion, the maternity and child welfare centres are now strong enough to keep their hold when this form of assistance is withdrawn, or rather when it is reduced to a minimum and kept strictly controlled."

Similar experiences have led to similar conclusions in America.

In the latter part of his history Dr. Niven has a good deal to say about health visitors and the value of their work, which was a subject of special investigation in 1911. At that time the training would be more elementary than now, and the period inquired into was too short to allow a final conclusion, but "the investigation brought home to us the vital need for constant supervision and unceasing training of the whole staff." He was struck by failures to appreciate the importance of regular and accurate weighing of children, and he concludes epigrammatically that "a good portable weighing machine is the clinical thermometer of the health visitor." In reviewing the present position, however, he holds that much success has been due to the house-to-house visits of health visitors, and the associated education of mothers at the maternity and child welfare centres.

There is temptation to add to these notes, but space forbids. The Corporation of Manchester is to be heartily congratulated on having had Dr. Niven as its medical officer for nearly thirty years, whilst Dr. Niven is to be congratulated on the completion (officially only) of a splendid life-work, and on the health annals which he has put on permanent record at its conclusion. His colleagues, we are sure, will miss him sorely, but they will hope that he may be long spared to encourage and advise those who are still in the fighting line.

According to recent statistics the mortality from diabetes in the United States is much higher in the white population in the north-eastern States than in the south and west. New York has 22 deaths per 100,000 inhabitants due to this cause annually, while Tennessee has only 6. Negroes show little susceptibility to diabetes in contrast with the Jews and Irish, who pay a heavy tribute to the disease in New York and New Jersey.

<sup>1</sup>Observations on the History of Public Health Effort in Manchester. By James Niven, M.A., M.B., LL.D. Manchester and London: John Heywood, Ltd. 1923. (Med. 8vo, pp. 230.)

should be given to the practitioner to be present at all operations and *post-mortem* examinations in which he is personally interested. This would not only help us in our work, but would bring us into such closer touch with the hospital that its success and welfare would be of much keener interest to us all.

Where a hospital is staffed only by general practitioners it could with advantage be affiliated with one or more of the larger hospitals of our great towns. Some of the junior members of the staffs of the latter could be asked to join those of the smaller in a consulting capacity for the benefit of the staff and the local practitioners. The pathological, clinical, and biochemical resources of these larger hospitals could also be made more available than they are now for the smaller and there should be the closest co-operation between us—the general practitioners—and them.

Medicine becomes more complex year by year; all sciences have become ancillary to it, and the full understanding of our present-day knowledge or theories has long been an impossibility to any one intellect. At the best the light of new discoveries is dimmed before it reaches us, submerged as we are by the needs of those around us. Specialization has become a necessity and will ever become more so. Team work is the solution of our difficulties, and the closer the interlocking of the general practitioners, the hospitals, and our teaching centres with their laboratories, the more efficient this will be. With this we need increased keenness amongst ourselves, and a better knowledge of general practice amongst the specialists gained (may I suggest it in all humility?) by graduation in the hard school of general practice itself.

We handicap ourselves, too, by insufficient study; indeed, many of us have little time for it and so must try to read wisely. Our JOURNAL each week keeps us up to date. Then we should never let our knowledge of surface anatomy get rusty, and a knowledge of modern physiology in its relation to practice is now a necessity.

Within our domain there are many forests of ignorance through which no trail has yet been blazed. Many have worked hard to find a pathway and yet success has not come. Why? In some instances, it may be, because they have not had the advantages we general practitioners have, they have not been able to see, as we do, the beginnings of things. We have failed because very few have ever tried. We all absorb a certain amount of clinical knowledge, we all gain experience, but how few make any record of such knowledge or experience. We just wander on, leaving no trace of our steps, and, who knows, perhaps often touching great things we do not feel or looking at discoveries we do not see. Can we alter this?

Of course, medicine and its practice is more than a means to live to most of us; it is a hobby. No men talk more proudly amongst themselves than general practitioners. Let us go further and have a hobby within our hobby and use the Association for its purpose. Each Division, or better, each Branch, could make some subject its special study as a Division or Branch. Certain meetings could be set aside for consideration of that study. Every member could collect some useful information to be reported and discussed at these meetings. One or more members could act as registrars for the collection and classification of the information supplied. One line of investigation after another could be carefully followed out and the proper teams chosen to carry any part of the work which was beyond our capabilities. These meetings would become real live things in which everyone who would could have a share; the British Medical Association would be not a thing apart from us but of daily interest to us and its power for good unassailable.

#### *Suggestions for Collective Investigation.*

What kind of work should we take up? Under the directorship of Sir James Mackenzie at St. Andrews an attempt is being made to understand the mechanism of early symptoms. Could we help? We have a large field, a great organization behind us, and in any such endeavour could, I hope, have the co-operation of many keen young men in active general practice, especially of those in rural districts who have or are likely to have the opportunity to watch the same patients for a long series of years. In addition our experience is not only clinical but therapeutic as well.

The type of disease we meet with is changing. Why? Some diseases are becoming less frequent, others more so. Why? Is the diminution in the frequency of rheumatic fever a result of the more efficient treatment of disease of the nose and throat in children? Are those who specialize in the removal of tonsils and adenoids greater benefactors than some may think? What is the influence of tonsil and adenoid operation on subsequent attacks of diphtheria? Is there any familial relationship between migraine and epilepsy? Why not study a symptom—for instance, cough; or rhythm in disease; or hypertension and its sequel arterio-sclerosis? How do they begin and what are their antecedents?

But I think that for us the great problem of all is malignant disease. Is it becoming more frequent as a whole? Is cancer of the skin diminishing and that of other organs increasing in frequency? What are its antecedents? What kind of person becomes its victim: rich or poor, hard-working or indolent, healthy or weakening? What about environment? Are there after all such places as cancer houses? Cancer is a problem at which many have worked hard for a large number of years and yet remains unsolved. Perhaps if we general practitioners were to take a hand in the game, investigate its antecedents much more carefully than we have ever done before, and pool the results of our clinical experiences, we might be of some service and able to throw some ray of light on the problem which would lead to the prevention of the disease if not its cure.

How should we set to work? I would suggest that we form a small committee to discuss this and draw up a scheme for submission to the Divisions of our Branch. The Branch could undertake some investigation as a whole or the Divisions work independently, each at subjects which perhaps for some local reason made a greater appeal to their members. The next step would be to define carefully our terms so that all those taking part would have the same perception of our subject and all travel the same road. Next we should have to draw up carefully as complete a questionnaire as possible, modifying it afterwards according to the dictates of experience. These forms would be sent out to all those willing to join in the work and when completed would have to be returned to the acting registrars, who would briefly report on them at our meetings; special meetings could be set apart for their discussion.

To carry on an investigation of the kind I have tried to sketch is the birthright of our profession, particularly of our Association. It is ours for the taking; it means hard, persistent, conscientious work, spread, maybe, over many years. It is in the power of each of us, if we try, to cut some notch in the trail through the forest of our ignorance by which those who follow can see their way and finally make a broad sunlit highway where now is only darkness.

## British Medical Association.

### CURRENT NOTES.

#### The Referendum in South Africa.

THE result of the recent referendum to the medical profession of the Union of South Africa has been announced as follows by the Referendum Subcommittee of the South African Committee:

|                                 |     |     |     |       |
|---------------------------------|-----|-----|-----|-------|
| Total number of votes recorded  | ... | ... | ... | 1,288 |
| Neutral or "Prefer not to vote" | ... | ... | ... | 7     |
| Returned "Address unknown"      | ... | ... | ... | 76    |
| Not returned in any way         | ... | ... | ... | 299   |

Total number of voting cards sent out ... 1,670

|                                                             |     |     |     |       |

|                                                             |     |     |     | 1,288 |

Majority in favour of S.A.M.A., with affiliation ... 190

It will be remembered that the following resolutions were adopted by the South African Medical Congress in

effort is being made to induce every professional, commercial, and municipal establishment in the area to adopt the scheme. The Joint Hospitals Council of Sheffield has distributed the grant made by the Voluntary Hospitals Commission to Sheffield hospitals; has set up the Sheffield Voluntary Hospitals Committee to advise the Commission; arranged during last winter a series of health lectures through a joint advisory committee on health education; and carried out active propaganda in connexion with its activities. The work of the Sheffield Joint Hospitals Council will be matched with great interest, the more so because in many particulars it transgresses the lines laid down by various bodies for such efforts; but in any case the experience of Sheffield will be of great value to voluntary hospital managers generally.

SHEFFIELD JOINT HOSPITALS COUNCIL.

The "penny in the pound" contributions are collected from employers of employees contributing to hospitals. The first annual report of the council has just been issued, and from this and news sheets published for propaganda purposes it is possible to obtain information as to the nature and extent of the scheme. The council includes representatives of the corporation, the Cutlers' Company, the University, the hospitals, the Edgar Allen Institute, boards of guardians, the Trades and Labour Council, the Insurance Committee, the British Hospitals Association, the Hospital Sunday Fund, the press, and the contributors, together with six "general" members. The work of the council is managed through seven committees. The president of the council is Councillor Mr. Hamberstone, J.P. The "penny in the pound" contributions are collected

on children's diseases will be given at the Victoria Hospital for Children, from October 8th to 28th, and in ophthalmology at the Royal London Ophthalmic Hospital, from October 8th to November 3rd. The National Hospital for Diseases of the Heart will give a fortnight's course on cardiology, and St. Mark's Hospital for Diseases of the Nectum on proctology, respectively, from October 15th to 27th. Copies of the syllabus and further particulars regarding any of the above courses will be forwarded on application to the Secretary to the Fellowship of Medicine, at No. 1, Wimpole Street, London, W.1.

Small-pox has again appeared in the metropolis, eight cases having been recognized between September 7th and 11th. They are widely distributed in Camberwell, Westminster, Raddington, Finsbury, Greenwich, Lewisham, and Willesden. A common source of infection has so far been discovered in four of them. A lady recently arrived from Spain and stayed for a short time at an hotel in the West End. She was indisposed, but was not seen by a medical man, and suspicion was not aroused until a maid who had waited on her was found to be suffering from small-pox. The lady had left the hotel, but was discovered staying with relatives. The house was visited by the medical officer of health, who found that the lady's sister was also suffering from small-pox. Further inquiry resulted in the finding of two other cases, contacts with the hotel case. At the time of writing the source of infection of the three additional cases has not been ascertained, but one of them may belong to the group in question. Meantime, all the known cases have been removed to hospital. No official statement has been made as to the type of the disease, but certain of the cases are said to be severe, and the fact that the infection came from the Continent makes it not difficult to believe in severity of type. It may be safely assumed that inquiries are being actively made as to contacts and that every precaution is being taken by the authorities. In the meanwhile it ought not to be necessary to emphasize the crucial

## Naval and Military Appointments.

### ROYAL NAVAL MEDICAL SERVICE

The following appointments are announced by the Admiralty: Surgeon Commanders R. H. St. B. E. Hughes to the *Excellent*, temporary; F. G. H. R. Black to the *Pembroke* additional for Chatham Dockyard, temporary. Surgeon Lieutenant-Commanders G. L. Ritchie, M.C., to the *Impregnable*, W. H. Sinclair-Loutit, R. Buddle, O.B.E., P. N. Bilton, O.B.E., W. J. Morris, J. F. Pace, J. F. M. Campbell, M. B. Macleod, and G. W. Woodhouse to the *President* additional for five months' course of instruction at R.N. College, Greenwich. Surgeon Lieutenants R. V. Higgins to the *Queen Elizabeth*. Mr. K. V. Francis has entered as Surgeon Lieutenant for short service and appointed to the *Victory*, additional for R.N. Hospital, Haslar, additional for course.

### ROYAL ARMY MEDICAL CORPS.

The following Captains are seconded for service with the Egyptian Army: D. C. Bowie, J. O. Collins, J. J. Magner, M.C. Temporary Captain N. Leonard relinquishes his commission and retains the rank of Captain.

### ROYAL AIR FORCE MEDICAL SERVICE.

Flight Lieutenant J. J. Walsh to No. 7 Squadron, Bircham Newton.

### TERRITORIAL FORCE.

#### ROYAL ARMY MEDICAL CORPS.

Captain N. M. Fergusson to be Major.  
Captains W. M. Wilson and E. W. Horrington, having attained the age limit, are retired and retain the rank of Captain.  
Lieutenant (temporary Captain) F. J. Cleminson relinquishes his commission and is granted the rank of Captain.  
Stanley McC. Kirk to be Lieutenant.  
*General Hospitals.*—Lieut.-Colonel Sir Ewen J. Maclean, having attained the age limit, is retired and retains the rank of Lieut.-Colonel. The following officers relinquish their commissions and retain their rank except where otherwise stated: Major E. O. Bevers, Major F. C. Pybus, Captain H. M. Clarke, Captain P. H. Green and is granted the rank of Major, Captain J. A. Gunn.  
*Sanitary Companies.*—Captain H. Duguid relinquishes his commission and retains the rank of Captain.

## VACANCIES.

ABERYSTWYTH INFIRMARY AND CARDIGANSHIRE GENERAL HOSPITAL.—House-Surgeon. Salary £200 per annum.  
BIRMINGHAM: QUEEN'S HOSPITAL.—Third Physician for Out-patients. Honorarium £50 per annum.  
CARLISLE: CUMBERLAND INFIRMARY.—Honorary Officer for the Ear, Nose, and Throat Department.  
CENTRAL LONDON OPHTHALMIC HOSPITAL, Judd Street, W.C.1.—(1) House-Surgeon, salary £150 per annum. (2) Junior House-Surgeon (non-resident), salary £50 per annum. (3) X-ray Officer, small honorarium.  
CHESTER ROYAL INFIRMARY.—Assistant House-Surgeon. Salary £150 per annum.  
CHURCH OF SCOTLAND FOREIGN MISSION COMMITTEE.—Medical Missionary (male) for Mission in Nyasaland.  
EAST AFRICAN MEDICAL SERVICE.—Medical Officers. Salary £600 per annum, rising to £900 with efficiency bars at £700 and £800.  
HACKNEY BOROUGH COUNCIL.—Medical Practitioner in connexion with Infant Welfare Centres. Remuneration £1 11s. 6d. per attendance.  
IPSWICH COUNTY BOROUGH.—Senior Assistant Medical Officer of Health and Assistant School Medical Officer. Salary £600 per annum.  
LONDON COUNTY COUNCIL.—Seventh Assistant Medical Officer in the Mental Hospital Service. Salary £300 per annum, rising to £400.  
LONDON JEWISH HOSPITAL, Stepney Green, E.1.—(1) Honorary Assistant Physician. (2) Honorary Surgeon. (3) Out-patient Assistant, salary £100 per annum.  
MANCHESTER: ANCOATS HOSPITAL.—(1) Resident Medical Officer. (2) Medical Registrar. Salary £200 and £100 per annum respectively.  
MANCHESTER ROYAL INFIRMARY.—Surgical Tutor (non-resident). Salary £30 per annum.  
MIDDLESEX HOSPITAL, W.1.—Radium Officer. Salary £300.  
MOUNT VERNON HOSPITAL FOR DISEASES OF THE CHEST, Northwood.—Assistant Physician.  
NATIONAL SANATORIUM, Benenden, Kent.—Resident Assistant Medical Officer (male). Salary £250 per annum.  
NEWCASTLE-ON-TYNE DISPENSARY.—Honorary Physician.  
PRINCE OF WALES'S GENERAL HOSPITAL, Tottenham, N.15.—(1) House-Surgeon. (2) House-Physician. (3) Junior House-Surgeon. (4) Junior House-Physician. Salary for (1) and (2) £150 per annum, and for (3) and (4) £110 per annum.  
QUEEN'S HOSPITAL FOR CHILDREN, Hackney Road, E.2.—House-Physician and Casualty House-Surgeon. Salary £100 per annum.  
ROYAL NATIONAL ORTHOPAEDIC HOSPITAL, Great Portland Street, W.1.—House-Surgeon. Salary £150 per annum.  
ST. PANCRA'S DISPENSARY, 39, Oakley Square, N.W.1.—Honorary Surgeon for Throat, Nose, and Ear Cases.  
SALFORD ROYAL HOSPITAL.—(1) Resident Medical Officer, £200 per annum. (2) House-Surgeon, £150 per annum. (3) Junior House-Surgeon, £150 per annum with £50 a year extra for V.D. Clinic. (4) Casualty House-Surgeon, £150 per annum.  
SEYMEN'S HOSPITAL SOCIETY, Greenwich.—House-Surgeon and House-Physician at Dreadnought Hospital. Salary at the rate of £150 per annum each and a proportion of fees.  
SHROPSHIRE ORTHOPAEDIC HOSPITAL, Gobowen, near Oswestry.—Girl Students to learn orthopaedic work. Salary, first year £16, and £20 second year.  
WALSILL COUNTY BOROUGH.—Assistant Medical Officer of Health (male). Salary £650 per annum, rising to £750.  
WESLEYAN MISSIONARY SOCIETY.—Doctor for service in a Leper Hospital, Diephalli, Hyderabad, South India.  
WEST AFRICAN MEDICAL TRUST.—Medical Officers. Salary £600 per annum, rising to £720, and if confirmed in appointment after probation £720, rising to £920.

WEST BROMWICH AND DISTRICT HOSPITAL.—Resident Assistant House-Surgeon (male). Salary £180 per annum.  
WINCHESTER: ROYAL HAMPSHIRE COUNTY HOSPITAL.—House-Physician (male). Salary £150 per annum.  
WOLVERHAMPTON AND STAFFORDSHIRE HOSPITAL.—Resident Medical Officer. Salary at the rate of £150 per annum.

*This list of vacancies is compiled from our advertisement columns, where full particulars will be found. To ensure notice in this column advertisements must be received not later than the first post on Tuesday morning.*

## APPOINTMENTS.

PANTING, Laurence C., M.D., B.Ch.Oxon., M.R.C.P.Lond., F.R.C.S.Eng., Honorary Consulting Surgeon to the Helston and District Cottage Hospital.  
ROBERTS, Charles, M.B., F.R.C.S., Medical Referee under the Workmen's Compensation Act, 1906, for County Court Circuits Nos. 5 and 8, and to be attached more particularly to the Oldham, Salford and Manchester County Courts vice Sir William Thorburn, deceased.  
CERTIFYING FACTORY SURGEONS.—H. Foxton, M.B., Ch.B.Leds., for the Uttoxeter District, co. Stafford; W. M. Mackay, M.B., Ch.B.Edin., for the Crook District, co. Durham.

## British Medical Association.

OFFICES AND LIBRARY, 429, STRAND, LONDON, W.C.2.

### Reference and Lending Library.

THE READING ROOM, in which books of reference, periodicals, and standard works can be consulted, is open to members from 10 a.m. to 6.30 p.m., Saturdays 10 to 2.  
LENDING LIBRARY: Members are entitled to borrow books, including current medical works; they will be forwarded if desired, on application to the Librarian, accompanied by 1s. for each volume for postage and packing.

### Departments.

SUBSCRIPTIONS and Manager. Teleg. ary and Business don).  
MEDICAL SECRETARY (London).  
EDITOR, *British M.* (London).  
Telephone number for all departments: Gerrard 2630 (3 lines).

SCOTTISH MEDICAL SECRETARY: 6, Rutland Square, Edinburgh. (Telegrams: Associate, Edinburgh. Tel.: 4351 Central.)  
IRISH MEDICAL SECRETARY: 16, South Frederick Street, Dublin. (Telegrams: Bacillus, Dublin. Tel.: 4737 Dublin.)

### Diary of the Association

SEPTEMBER.  
17 Mon. London: Library Subcommittee, 2.30 p.m.  
21 Fri. London: Science Committee, 2.30 p.m.  
North Wales Branch: Special Autumn Meeting, Imperial Hotel, Llandudno, 2.15 p.m. Report of Branch Council. Address by Sir Ewen Maclean, M.D., F.R.C.P., on "Puerperal Sepsis in Wales."  
25 Tues. London: Central Ethical Committee, 2 p.m.  
London: Organization of Medical Students Subcommittee, 2.30 p.m.  
London: Grants Subcommittee, 3 p.m.  
26 Wed. London: Hospitals Committee, 2.30 p.m.  
27 Thurs. London: Arrangements Committee, 2.30 p.m.  
28 Fri. London: Public Health Committee, 2.15 p.m.  
OCTOBER.  
2 Tues. London: Organization Committee.  
3 Wed. London: Medico-Political and Parliamentary Committee, 2.30 p.m.  
4 Thurs. London: Insurance Acts Committee, 12 noon.  
5 Fri. London: Dominions Committee, 2.30 p.m.

### POST-GRADUATE COURSES AND LECTURES.

WEST LONDON POST-GRADUATE COLLEGE, Hammersmith, W.—Mon., 12 noon, Dr. Simmons: Applied Anatomy. Tues., 12 noon, Dr. Burrell: Chest Cases. Wed., 10 a.m., Dr. Saunders: Medical Diseases of Children. Thurs., 10 a.m., Dr. Grainger Stewart: Neurological Department. Fri., 2 p.m., Dr. Burrell: Medical Out-patients. Sat., 10 a.m., Dr. Saunders: Medical Diseases of Children. Daily 10 a.m. to 6 p.m., Sat. 10 a.m. to 1 p.m., In- and Out-patients, Operations, Special Departments.

### BIRTHS, MARRIAGES, AND DEATHS.

*The charge for inserting announcements of Births, Marriages, and Deaths is 9s., which sum should be forwarded with the notice not later than the first post on Tuesday morning, in order to ensure insertion in the current issue.*

#### BIRTHS.

CARTER.—On September 5th, to Gladys, wife of O. C. Carter, M.B., B.S.Lond., of Bournemouth—a daughter.  
GALLOWAY.—To Dr. and Mrs. Galloway, Western House, Southall, a daughter on September 6th, 1923.  
HUGHES.—On September 6th, at Heylands, Chagford, Devon, to Armored, the wife of Dr. H. L. Glyn Hughes, D.S.O., M.C., a daughter.

#### MARRIAGE.

HAIGH-KRUGER.—On September 8th, at Geneva, William E. Haigh, F.R.C.S., D.T.M., Epidemic Commission, Health Section, League of Nations, to Catherine Marguerite, daughter of the late Pastor Frederic H. Kruger, Société des Missions Évangéliques, Paris, and of Madame Kruger, 22, Schertlinggasse, Basle.

#### DEATH.

WOODHOUSE.—On September 9th, at Dawley, Shropshire, Charles Herbert (Tommy) Woodhouse, only son of H. C. Woodhouse, M.B., and Mrs. Woodhouse.

intention of taking a census in 1926. A notable feature of the report is its indication of a diminishing death rate from pulmonary tuberculosis in Belfast. For four years in succession the mortality has declined. In 1922 it was 1.5 per 1,000, a reduction of 45 per cent. as compared with 1850, when the death-rate was 7.4 per 1,000. A corresponding fall occurred also in non-pulmonary forms of tuberculosis; here the rate now stands at 0.56 per 1,000, as compared with 0.74 per 1,000, a reduction of more than 50 per cent. since 1918. These figures reflect credit on the department and give promise of still greater success in the future, both among adults and children. Dr. Trimble praises his tabulated analysis of movement for combating tuberculosis in Belfast, the method by which patients come into touch with the department, and the resources at his disposal for the treatment of the disease. It is now seven years since an agreement was entered into between the Belfast Corporation and the Belfast Insurance Committee, whereby the Corporation undertook the treatment of all tuberculous insured persons within the area. In 1918 the present Central Tuberculosis Institute was opened; in 1921 the Municipal Hospital for Tuberculous Children, with an open-air school in its grounds for contacts of tuberculous patients, was established. Each patient before being examined at the tuberculous institutes must bring with him a letter from a medical practitioner stating that in his opinion the person named is suffering from tuberculosis and requires treatment. If, after examination, the patient is found to be suffering from tuberculosis, or from suspicious symptoms, he is placed under treatment either with his own doctor, or at one of the institutes, or at the sanatorium. Of the patients found to be suffering from tuberculosis during the year more than 42 per cent. had had an admitted personal association with tuberculosis amongst other members of their families. In many cases, as the result of infection, whole families in Belfast have been wiped out by the disease, though such disasters are becoming less frequent. But (adds Dr. Trimble) the fact that so large a percentage of detected tuberculosis is apparently traceable to association with other known cases makes the continuous supervision of the home conditions by the nurse all the more necessary. As might be expected, tuberculosis falls most heavily on the older, poorer, more land-locked, and more densely populated districts of the city. During the year an educational propaganda was continued by means of illustrated lantern lectures, and Dr. Trimble looks forward to the development of this in a much more ambitious and more comprehensive scheme in the near future. His report ends on a hopeful note:

"When time is given for the work which is now being done amongst children to mature, I am confident that the death rate from tuberculosis will be declining rapidly, and that which to-day is designed a 'problem' will to-morrow take its place along with the 'problems' of plague, typhus fever, and small-pox."

## Scotland.

SCOTTISH ASYLUMS' PATHOLOGICAL SCHEME.

The Board of the Scottish Asylums' Pathological Scheme in its report for 1922 records high appreciation of the valuable research work carried out by the late Dr. Ford Robertson, whose lamented death took place on July 17th of this year (an obituary notice appeared in our issue of August 11th, p. 264). Dr. Ford Robertson had acted as superintendent of the Laboratory since the commencement of the Scheme in 1897; under his able direction the Laboratory increased its scope and usefulness and attained its present important position. His report indicates that the work of the Laboratory proceeded along the usual lines during the year under review. Many specimens sent from the contributing asylums were examined and reported on: these examinations consisted of a complete bacteriological analysis of the flora of the intestinal tract, urine, and nasopharynx, representing a vast amount of detailed work. Several visits were paid by Dr. Ford Robertson to asylums,

## THE INNERVATION OF THE UTERUS.

## Correspondence.

to guide and advice as to bacteriological examinations and treatment. His research work in 1922 was mainly directed to further investigations into the toxic origin of dementia praecox. As a result of his extended study and experience he was able to report considerable progress in the treatment of this malady by therapeutic immunization with suitable vaccine. His own observations confirmed very fully the great frequency of deep abscess reported by Dr. Henry A. Cotton in dementia praecox reported by Dr. Henry A. Cotton out by Dr. Ford Robertson during recent years in the Scottish Asylums Laboratory convinced him that in all cases of dementia praecox there was a severe condition of chronic intestinal infection by anaerobic bacteria with distinct neurotoxic properties. "I cannot carry these investigations much further in the Laboratory alone; the time has come when the efficacy of the therapeutic measures that seem to be clearly indicated must be tested on a large scale in the asylums." He therefore appealed to the Board to provide him with a laboratory or wards for the therapeutic investigation, in order that early cases of dementia praecox could be treated by the methods found successful in private cases.

It possessed certain properties and a certain mass, and was the ultimate piece of stuff of that particular element; it was regarded by the general student and investigator as not only indivisible but homogeneous. The new work has proved that the atom is not homogeneous, but is built up of particles of positive and negative electricity arranged in an orderly way. Moseley, whose death was among all the losses to science inflicted by the war probably the greatest, had found a new order for the elements in atomic number, mounting by a whole number which varied by unity in passing from hydrogen 1 to uranium 92; it revealed a relation of unforeseen simplicity between the elements. Most of the numbers between 1 and 92 were occupied by known elements, and among the blanks one at least has been filled by hafnium, to the discovery of which Coster and Hevesy of Copenhagen were led by the vacancy for the atomic number 72 disclosed by Moseley's law. This law has thus already not only explained old facts, but pointed the way to the discovery of new—the two supreme tests of the validity of a scientific hypothesis.

Moseley worked on the theory of the nuclear atom, which is that an atom consists of a very dense nucleus, a particle of positive electricity (proton) surrounded by a planetary system of particles of negative electricity (electrons). The first atomic number is occupied by hydrogen, which has a nuclear charge of one, and one electron moving in an orbit, approximately circular, around it; the second, helium, has a nuclear charge of two, and two electrons. These two electrons, the "K" group, are common to all the elements with an atomic number above hydrogen; new groups are added as the atomic number rises until we reach uranium, which we must conceive as having at its centre a minute nucleus surrounded by swirling groups of 92 electrons moving at varying rates, the speed depending on their closeness to the nucleus. So that while the outermost electrons have a minimum speed of something over 1,000 kilometres a second, the innermost "K" electrons have a speed of more than 150,000 kilometres a second, or half the speed of light.

The electrons occupy, but do not fill, a volume very large compared with that of the nucleus. Dr. Aston, in an address to the British Association when it met in Hull last year, said that even in the heaviest atom known the constituent charges failed to fill even the million-millionth part of this whole volume. The theory of the nuclear atom was put forward by Rutherford in 1911, and the nucleus must be conceived as extremely small compared with the whole atom; thus Dr. Aston said: "If in the atom of helium (atomic weight 4, atomic number 2) we take the nucleus consisting of four protons and two electrons as represented by a rather large pea, its planetary electrons may be represented on the same scale as two rather smaller peas revolving around it at a distance of a quarter of a mile." As this quotation from Dr. Aston suggests, physicists are carrying their inquiries still further and are attempting to ascertain the structure of the nucleus. Already certain investigations by Sir Ernest Rutherford himself and Dr. Chadwick leave very little room for doubt that hydrogen nuclei form the essential part of the nuclear structure. The conclusion is forced that the nucleus of a heavy atom is a very complicated system. When the mass of the nucleus is compared with its volume it seems certain that its density is many billion times that of our heaviest element, yet it is probably a discontinuous structure occupied but not filled by

the incredibly minute building units, the protons and electrons, in ceaseless rapid motion controlled by their mutual forces.

It has been supposed that hydrogen may be built up into helium; were this to occur energy would be set free, and calculation shows that the amount so liberated would be prodigious; if the hydrogen contained in a pint of water could be transmuted the energy furnished would, Dr. Aston has estimated, be sufficient to propel a big liner across the Atlantic and back again at full speed. But there is no certain experimental evidence that helium can be formed from hydrogen; the process may be going on in the sun, and it has been calculated that this synthesis of helium need only take place slowly in order to maintain the present rate of radiation from the sun for periods of the order of a thousand million years. Sir Ernest Rutherford discourages the extravagant hypotheses put forward some ten years ago with regard to the stores of energy hidden in the atoms of an element. He, on the contrary, suggests that uranium and thorium represent the sole survivals in the earth to-day of types of element common in the long-distant ages when the atoms now composing the earth were in course of formation. Some atoms of uranium and thorium have, owing to their slow rate of transformation, survived, and may be regarded as having not yet completed the cycle of changes which the atoms of other elements have long since passed through. On this view the presence of a store of energy ready for release is not a property of all atoms, but only of a special small class, like the radio-active atoms, which have not yet reached the final state for equilibrium.

Though Sir Ernest Rutherford dealt with an extremely complicated subject, involving conditions of matter very difficult to visualize, it is stimulating to read at first hand the views of one who has himself had so large a part in the astonishing progress which has been made. Every civilized nation has taken an active part in the study of the problem, but, as he said, "we may be justly proud that this country has made many fundamental contributions." He did well to include the British dominions overseas, where workers have not been behindhand with their contributions; and it is, we may hope, significant of the oneness of the British Empire that Professor Rutherford himself is a New Zealander, and that he was Professor of Physics in McGill University, Montreal, before he became professor in the same subject in the University of Manchester, a post he only vacated four years ago to succeed Sir J. J. Thomson as Professor of Experimental Physics and Director of the Cavendish Laboratory of the University of Cambridge.

#### THE AUSTRALASIAN CONGRESS OF THE BRITISH MEDICAL ASSOCIATION.

THE Australasian Medical Congress—the first to be held under the direction of the Federal Committee of the British Medical Association in Australia—will open in Melbourne on November 12th; it will meet under the presidency of Mr. G. A. Syme, M.S., F.R.C.S., and the parent Association will be fitly represented by Sir William Macewen, F.R.S., the distinguished Regius Professor of Surgery in the University of Glasgow, and President of the British Medical Association last year. He is expected to arrive in Sydney about October 17th, by the mail boat from San Francisco, and will be the guest of Sir Walter Davidson, Governor of New South Wales. He will be entertained at dinner by the members of the Glasgow University Club on October 22nd, and by the New South

out and the nature of their diseases mentioned; short intervals were allowed for private prayer. It was also stated that one or two persons who had been prayed for on a previous occasion were in better health. There was no rhetorical or emotional appeal.

The position of the medical profession is undoubtedly difficult. On the one hand, it is anxious not to offend the faith of many of its own members or of the general public; on the other hand, it will be generally disposed to accept the conclusion of the Committee of Inquiry into spiritual, fair, and mental healing, which made a preliminary report in 1914 to the effect, as was recalled in the document of September 8th, "that 'faith' or 'spiritual' healing, like all treatment by suggestion, can be expected to be permanently effective only in cases of what are generally termed 'functional' disorders. The alleged exceptions are so dispensable that they cannot be taken into account."

The object of this letter is to suggest that the Committee, which reported its inquiry owing to the war, should now be reconstituted, and, as was suggested in the report of 1914, go on to direct its attention to a careful inquiry "into the evidence for cases of asserted cure by 'spiritual' or 'mental' healing of organic or other serious disorders submitted for investigation." I do not at the moment recall the constitution of the original Committee, but it contained both clerical and medical members, and I believe I am right in saying that Bishop Ryle, Dean of Westminster, was its chairman. He has shown that his interest in the matter continues by allowing an address on the subject to be given in the Abbey by the Rev. R. C. Griffith. Would it not be well to ask Bishop Ryle to start the Committee again?—September 8th.

M. D.

Sir,—In your annotation (September 8th, p. 428) on the above subject you refer to the address by the Rev. R. C. Griffith delivered in Westminster Abbey, and give the following quotation from his remarks: "I myself," he said, "have seen blind people see. We have seen one with a withered arm for sixteen years hanging at her side suddenly shoot it out perfectly whole. We have seen convalescences disappear in twenty minutes." I cannot help feeling that a great boon would be conferred upon all interested in the subject—and the circle of inquirers is a world-wide one, including many of a very perplexed profession—if the challenge, for such it might reasonably be regarded, were taken up and Mr. Griffith asked for some reasonable proof of the statements he makes regarding the three particular classes of cases he quotes. I presume the first stage of the inquiry would be for Mr. Griffith to supply the names and addresses of the patients cured. These could be given in strict confidence. This information obtained, the patients would be asked to give the names of their medical attendants prior to their cure. As medical men we know that such statements as those made by Mr. Griffith cannot wholly be accepted on the basis which he wishes or intends should be ascribed to them, however much we may be in sympathy with such supernatural intervention if it can only be proved to be real. As Mr. Macadam Eccles indicates, diagnosis is an essential factor in determining what value may be attached to cures that on the face of them appear to be miraculous. The question, therefore, is primarily and essentially a medical one.—I am, etc., A. LAWEST MAYLAND, Retiristide, Glasgow, Sept. 19th.

THE DIFFERENTIAL DIAGNOSIS OF SMALL-POX AND CHICKEN-POX.

Sir,—I am fully able to corroborate the points emphasized by Dr. Brand in your issue of July 28th (p. 160), on the differential diagnosis of small-pox and chicken-pox, from my experience of these affections, comprising almost 14,000 cases of small-pox and over 2,000 cases of chicken-pox, during thirty-four years at the Arthur Road Hospital, Bombay. The diagnosis of chicken-pox does not rest upon the absence of early constitutional disturbances, nor upon the number of vesicles, nor their distribution, but solely upon the

the characteristics of the eruption. These are: (a) The more or less elliptical or oval shape, that may or may not be surrounded by an angry reddish areola; (b) the uniform local character of the vesicle, that can be emptied of its contents by a single puncture, completely flattening it out, leaving the thin epidermis over its base; (c) the simultaneous presence, on one and the same part of the body, of papules, early and late vesicles, dried-up and encrusted vesicles, and even falsely umbilicated vesicles—a combination that has never been noted, to my knowledge, in small-pox; (d) the desiccation of the vesicles without suppuration within two or three days or even earlier; and lastly, (e) the appearance of successive crops of vesicles over three to five days, each crop of eruptions being preceded or accompanied by elevation of temperature that may reach 103° to 104° F., especially in children.

One of the chief stumbling blocks, for those unfamiliar with chicken-pox, is the presence of false umbilication. That phenomenon occurs in chicken-pox from the rupture of the vesicle, with or without purulation, through friction with the clothes or scratching, and if examined closely it will be found that the vesicle is not full as in small-pox, but empty, and the epidermis is becoming incised over the flattened base of the eruption presents this deceptive appearance, which is further accentuated by the dark crust of the apex of the vesicle in its centre. Chicken-pox, as at times observed in Bombay, is by no means such a mild infection. Often and often one meets with severe constitutional disturbances, high fever, delirium, and even convulsions in children, and when followed by the eruption the physician may be led away into declaring it small-pox. But the early vesiculation and drying up, the persistence of plicae, and the characteristics above referred to, should enable one to arrive at a correct diagnosis. For confirm, in the preponderatingly larger number of cases, the patient appears at the hospital with a copious crop of vesicles without any previous history of high fever, or even any fever at all preceding it. Such eruption may also be observed on the palate and buccal mucous membrane simultaneously. As to the gravity of small-pox, it is a factor well known to all who have to deal with it, that the initial appearance of even serious symptoms is no criterion of the severity of the disease, and that many a case that begins with apparently threatening symptoms eventually turns out to be a mild case. Lastly, the presence of lumbar pain is of indefinite significance in the diagnosis of small-pox among the generality of Indian patients, who will complain of pains all over the body.—I am, etc., N. H. CHOKSY, C.I.E., M.D., Late Assistant Health Officer in Charge, Arthur Road Infectious Diseases and Maratha Pines Hospital, Bombay. Bombay, Aug. 25th.

TESTS FOR DRUNKENNESS.

Sir,—Would some of your readers who have had special experience give us the benefit of their advice on the best tests for drunkenness? It is very important that doctors, who are so often called upon to decide the question of intoxication in motor drivers and others, should be sure of their ground. Recently a case was withdrawn by the police after their doctor had failed to satisfy the magistrate that the tests he had made were adequate. No any of your readers know the nature of the tests recently devised by the Danish Medical-Legal Society?—I am, etc., I. A. PARRY, Here, Sept. 6th.

\* The tests for drunkenness recently devised by the Danish Medical-Legal Society are the outcome of the law of 1921, which provides for the permanent withdrawal of the licences of motorists convicted of drunkenness while driving. In co-operation with the police, the Danish Medical-Legal Society decided that it would be impracticable to carry out such tests as the examination of the blood or urine for alcohol, and the system to which our correspondent refers is based on the ordinary clinical tests. The chief merit of the system would seem to be its orderliness.

At that time (seventeen years ago) well over 300 fatalities from eating it had been recorded in medical literature. Dr. Ford concluded that the active principle of the plant was an alkaloid—"amanita toxin"—a heat-resistant substance devoid of haemolytic properties. Unfortunately no antidote is known, and treatment must follow general lines; a vivid account of the toxic symptoms is given in Mr. Ramsbottom's book. *Amanita muscaria*, with its bright red top studded with red spots, is of course unlikely to be eaten in mistake for the common mushroom; it contains muscarin, myceto-atropine, and choline, and is therefore very poisonous, though far less so than *A. phalloides*.

#### ANTHRAX IN TANNERIES.

THE International Labour Office, as a result of a resolution passed at the third session of the International Labour Conference held at Geneva in 1921, set up an Advisory Committee on Anthrax, which, at a meeting in London in December, 1922, proceeded to examine the problem of disinfection of hides and skins. It has long been known that the principal risks of infection from anthrax arose from handling these articles of commerce, but hitherto no process of disinfecting them which offered adequate protection against anthrax spores has been determined. The International Labour Office consequently secured the collaboration of Dr. H. Leymann of the Federal Ministry of Labour, Berlin, for many years recognized as a leading authority in the field of industrial hygiene, to report on the occurrence of anthrax among workers in the tannery industry and on the most modern methods of disinfecting hides before or during the process of tanning. His investigations are now published by the International Labour Office.<sup>1</sup> The statistics of the incidence of anthrax tabulated by Dr. Leymann, although they refer to Germany only, are of much interest and value. They show clearly that the chief sources of infection are imported ox-hides and cow-hides; and that during the years of the war and after, when the importation of hides practically ceased or was greatly restricted, the cases of anthrax decreased to a remarkable extent. In the period 1910-21 there were 1,575 cases, of which 249 were fatal, but while the number yearly from 1910 to 1914 was approximately 200, in 1915 there were only 67 cases, and in 1919 only 18. In Germany compulsory notification of anthrax is in force, and from information obtained in this way it was shown that outbreaks occurred amongst cattle pastured in valleys of rivers and streams on whose upper reaches tanneries which dealt with imported hides and skins were established. Incidentally we may note that many years ago a similar observation was made in connexion with the pollution of the river Severn in England. Micro-organisms from town drainage found their eventual resting place in the vegetation of the river banks many miles down stream, and anthrax from tanneries in this way infected the cattle grazing on the river pastures. The problem, therefore, is how hides can be effectively disinfected before they are handled for tanning. Dr. Leymann tested three processes: the Seymour-Jones, which consists in dipping the hides for twenty-four hours in a solution of 0.02 per cent. of mercury chloride and 0.9 per cent. of formic acid; the pickling process of treating them with a solution of 1 to 2 per cent. of hydrochloric acid to which 10 per cent. of common salt has been added, and kept at a temperature of 20° to 40° C., and the lye process, the basis of which is a 0.5 per cent. soda lye with 1 to 10 parts in 100 of common salt added. Dr. Leymann's conclusions are that the Seymour-Jones process is uncertain, that the pickling process gives good results, and is eminently suitable for disinfection at ports of entry and at industrial centres where there are

special establishments, and that the lye process, which also gives good results, is simpler and more economical and consequently offers considerable advantages to smaller establishments. Detailed instructions for disinfection of hides by both these latter processes are given as appendices to the report, and the pamphlet thus contains matter that is of great importance not only to the tannery industry, but also to medical officers of health. Further practical measures of dealing with imported hides will depend on the drawing up of a list of countries in which anthrax is prevalent, and this is being considered by the Advisory Committee. The general subject is being discussed at a meeting this week of the international committee of experts appointed at the Labour Conference of Washington in 1919, to deal with matters affecting the health of workers. The committee is composed of medical inspectors of factories and others possessing technical and scientific knowledge of industrial hygiene, drawn from a dozen countries; among the representatives of this country is Dr. T. M. Legge, chief medical inspector of factories. Another subject to be discussed at the meeting this week is the preparation of a schedule of unhealthy processes. This involves not merely the examination of the dangers to health involved in various processes, but the collection and study of all the available scientific and statistical information relating to each process. The list is already in an advanced stage, but before it is published the experts forming the present committee are to be asked to examine it in detail and to collaborate in ensuring its scientific completeness and accuracy.

#### THE SAVILE CLUB.

LAST year the Savile Club completed forty years of residence in 107, Piccadilly, a house bought from Lord Rosebery in 1882, although its existence under the name of the Savile dates from some ten years earlier. To celebrate the club's jubilee a history of its origin and development,<sup>1</sup> with a list of all who have been or are its members, and entertaining reminiscences of many of them, has been prepared, evidently by a loving hand, for it is a club beloved of its habitués. The handsome volume contains much that is of interest to medical men. It was the "Medical Club" to which the Savile may be said to owe its origin. In 1868 the Medical Club offered the Eclectic Club—incidentally both these clubs are defunct or have been submerged in other names—"a very pleasant and complete set of rooms" at 9, Spring Gardens, overlooking Trafalgar Square. The Eclectic, a night club but not of the modern variety, declined the offer, but some of its members thought better of it and took over the delectable premises with a view to forming a club "of such persons as are engaged in different ways of life, and deputed as it were out of the most conspicuous classes of mankind." The quotation, which is from the *Spectator* of April 9th, 1711, is given in a short preface to the history as indicating the dominant principle on which the Savile Club was founded—namely, the mixture of men of different professions and opinions, and a careful process of election. The list of members bears this out to a remarkable degree, for it contains the names of men who have become famous as statesmen, authors, editors, artists, composers, bishops, doctors, scientists, soldiers, and explorers. There is an imposing array of Fellows of the Royal Society. It has been said elsewhere that the Club was "a little place" for those aspiring to the dignity of membership of a certain club, reputed to be duller and more austere, to wait in. It has become a little place for them to return to for relaxation and conviviality. In 1871 the new club moved from Spring Gardens to 15, Savile Row, and took its present name then. It outgrew the premises in 1931

## THE BRITISH ASSOCIATION, LIVERPOOL.

## PRESIDENT'S ADDRESS

ON

## THE ELECTRICAL STRUCTURE OF MATTER.

THE annual meeting of the British Association for the Advancement of Science opened in Liverpool on Wednesday, September 12th, when Sir Ernest Rutherford succeeded Sir Charles Sherrington as President.

## INTRODUCTORY.

Sir ERNEST RUTHERFORD began his presidential address by recalling that when the British Association last visited Liverpool, in 1896, it met under the presidency of the late Lord Lister, whose memory is held in affectionate remembrance by all nations. His address, which dealt mainly with the history of the application of antiseptic methods to surgery and its connexion with the work of Pasteur, that prince of experimenters, whose birth has been so fittingly celebrated this year, gave in a sense a completed page of brilliant scientific history. At the same time, in his opening remarks, Lister emphasized the importance of the discovery by Röntgen of a new type of radiation, the  $x$  rays, which, as is now realized, marked the beginning of a new and fruitful era in another branch of science. The discovery had been published to the world in 1895, while the discovery of the radio-activity of uranium by Becquerel was announced early in 1896. Even the most imaginative of scientific men could never have dreamed at that time of the extension of our knowledge of the structure of matter that was to develop from these two fundamental discoveries; but in the records of the Liverpool meeting were to be seen the dawning of a recognition of the possible consequences of the discovery of  $x$  rays, not only in their application to medicine and surgery, but as a new and powerful agent for attacking some of the fundamental problems of physics.

In applied physics, too, 1896 marked the beginning of another advance. In the discussion of a paper which I, Sir Ernest Rutherford said, had the honour to read, on a new magnetic detector of electrical waves, the late Sir William Preece told the meeting of the successful transmission of signals for a few hundred yards by electric waves which had been made in England by a young Italian, G. Marconi. The first public demonstration of signalling for short distances by electric waves had been given by Sir Oliver Lodge at the Oxford meeting of this Association in 1894. It is startling to recall the rapidity of the development from such small beginnings of the new method of wireless intercommunication over the greatest terrestrial distances. In the last few years this has been followed by the even more rapid growth of the allied subject of radio-telephony as a practical means of broadcasting speech and music to distances only limited by the power of the transmitting station.

The rapidity of these technical advances is an illustration of the close interconnexion that must exist between pure and applied science if rapid and sure progress is to be made. The electrical engineer has been able to base his technical developments on the solid foundation of Maxwell's electromagnetic theory and its complete verification by the researches of Hertz, and also by the experiments of Sir Oliver Lodge in this university. The benefits of this union of pure and applied research have not been one-sided. If the fundamental researches of the workers in pure science supply the foundations on which the applications are surely built, the successful practical application in turn quickens and extends the interest of the investigator in the fundamental problem, while the development of new methods and appliances required for technical purposes often provides the investigator with means of attacking still more difficult questions.

This important reaction between pure and applied science is particularly manifest in the development of  $x$ -ray radiography for therapeutic and industrial purposes, where the development on a large scale of special  $x$ -ray

tubes and improved methods of excitation has given the physicist much more efficient tools to carry out his researches on the nature of the rays themselves and on the structure of the atom. In this age no one can draw any sharp line of distinction between the importance of so-called pure and applied research. Both are equally essential to progress, and we cannot but recognize that without flourishing schools of research on fundamental matters in our universities and scientific institutions technical research must tend to wither. Fortunately there is little need to labour this point, for the importance of a training in pure research has been generally recognized. Those who have the responsibility of administering the grants in aid of research for both pure and applied science will need all their wisdom and experience to make a wise allocation of funds to secure the maximum of results for the minimum of expenditure. It is fatally easy to spend much money in a direct frontal attack on some technical problem of importance when the solution may depend on some addition to knowledge which can be gained in some other field of scientific inquiry, possibly at a trifling cost. It is not in any sense my purpose to criticize those bodies which administer funds for fostering pure and applied research, but to emphasize how difficult it is to strike the correct balance between the expenditure on pure and applied science in order to achieve the best results in the long run.

## THE ELECTRICAL STRUCTURE OF MATTER.

Sir Ernest Rutherford then entered upon the main topic of his address, the great advance in knowledge of the nature of electricity and matter which justified the description of the period since the last Liverpool meeting as the heroic age of physical science.

Before the beginning of that period, he said, it had been perceived by the more philosophically minded that the periodic variations of the properties of the elements brought out by Mendeléef were only explicable if atoms were similar structures in some way constructed of similar material. At the same time the idea was generally gaining ground that an explanation of the results of Faraday's experiments on electrolysis was only possible on the assumption that electricity, like matter, was atomic in nature. The name "electron" had been given to this fundamental unit by Johnstone Stoney, and its magnitude roughly estimated, but the full recognition of the significance and importance of this conception belongs to the new epoch. In the early development of this subject science owes much to the work of Sir J. J. Thomson, both for the boldness of his ideas and for his ingenuity in developing methods for estimating the number of electrons in the atom, and of probing its structure. He early took the view that the atom must be an electrical structure, held together by electrical forces, and showed in a general way lines of possible explanation of the variation of physical and chemical properties of the elements, exemplified in the periodic law. The discovery of radium was a great step in advance, for it provided the experimenter with powerful sources of radiation specially suitable for examining the nature of the characteristic radiations which are emitted by the radio-active bodies in general. It was soon shown that the atoms of radio-active matter were undergoing spontaneous transformation, and that the characteristic radiations emitted—namely the  $\alpha$ ,  $\beta$ , and  $\gamma$  rays—were an accompaniment and consequence of these atomic explosions. The proof that the  $\alpha$  particle is a charged helium atom for the first time disclosed the importance of helium as one of the units in the structure of the radio-active atoms, and probably also in that of the atoms of most of the ordinary elements.

Not only, then, have the radio-active elements had the greatest direct influence on natural philosophy, but in subsidiary ways they have provided us with experimental methods of almost equal importance. The use of  $\alpha$  particles as projectiles with which to explore the interior of the atom has definitely exhibited its nuclear structure, and promises to yield more information yet as to the actual structure of the nucleus itself.

## Medicine.

### Treatment of Kala-azar.

151.

H. H. SHORTT and RAVI THAKUR SEN (*Indian Med. Gaz.*, July, 1933, p. 289) record the results obtained in the treatment of

kala-azar in the special Kala-azar Hospital at Shillong during the year 1932. Only those cases were treated which submitted to spleen puncture and in which the result of the course of intravenous injections of a 1 per cent. solution of sodium antimony tartrate in normal saline. These were given on every second day, commencing with 3 c.c.m. and rising to a maximum of 8 c.c.m. at a single injection, which was generally the sixth. Thereafter the above maximum dose was continued until the appearance of symptoms of intolerance, when treatment was abandoned or the dosage diminished according to individual indications. No intolerance was displayed in 35 per cent. of the cases, and in these administration ceased when signs of cure were manifested, as judged by gain in weight, improvement in size of the spleen, continued absence of fever, improvement in general blood condition, and negative microscopic and cultural results. Out of about fifty cases 50 per cent. were cured and 8 per cent. died; the remainder were relieved or discharged otherwise. With antimony antimony tartrate three cases were treated and cured, but there was nothing to indicate that this was superior in action to the sodium salt. To five cases urea was administered with striking results. The intravenous route was employed and the initial dose was 0.1 gram in cold sterile water, increasing at each injection, given on alternate days, by 0.05 gram, until a dose of 0.55 gram was reached and continued for subsequent doses. The advantages of this drug, in the cases observed, appeared to be the rapidity with which symptoms of the disease disappeared, the short period required for cure to be obtained—only two to three weeks as against an average of three months when sodium antimony tartrate is employed—and the absence of symptoms of intolerance. Intravenous injection of 1 or 1,000 formalin was tried in six cases without any apparent effect, and two cases in which trypan blue was used remained fatally. The authors consider that most cases of relapse are due to insufficient treatment in inherently obstinate types, and stress the necessity of the individual dosage and duration of treatment. For the preliminary diagnosis of a case spleen puncture, followed by microscopic examination of the slide, is recommended as the method of choice; cultural methods are chiefly of value in doubtful cases.

152.

### Tuberculous Paronychia.

J. H. STORES (*Arch. of Derm. and Syph.*, July, 1933, p. 44) reports a case of tuberculous paronychia with unusual features. The history commenced with what appears to have been an erythema nodosum of the legs, which disappeared in three or four days. Its appearance marked the beginning of a decline in general health, and fully two years later a lesion of the lower lip and paronychia of the right thumb developed. The infection spread progressively to several fingers on both hands. The process began at the tip of the digit (not in the base of the nail) and extended round the nail, which eventually became raised above the matrix by a growth of horny material. There was no special tendency to ulceration, no inflammatory area, and the condition did not at any time suggest a tuberculous one. At this period there was no cough, no chest or throat lesion, and no tuberculous reactions the von Pirquet test was positive. Death occurred three years from the onset of the erythema nodosum, and only during the last year did definite signs of tubercles develop in the abdomen and chest. This is one of several cases reported by the author, which, commencing in erythema nodosum, terminated in death by tuberculo-

153.

### Albuminuria in Adolescents.

B. FASKOORT McDONALD (*Med. Journ. Australia*, May 26th, 1933, p. 571) discusses clinically that form of albuminuria in adolescents in whom no renal disease is suspected. An otherwise unexplained headache, chronic indigestion, or general malaise may be associated symptoms, and the patient is run down, and with or without the presence of casts, especially granular casts in any number, ind-

157.

### Bronchial Asthma and Hay Fever.

A. A. KAMMEZ (*New York Med. Journ. and Med. Rec.*, June 20th, 1933, p. 137), in considering bronchial asthma and hay fever, with special reference to the treatment of non-specific cases, urges the necessity for obtaining a careful personal and family history and complete physical and x-ray examination, with laboratory examination of the urine, stool, and sputum, and, if indicated, the taking of cultures from the nose and tonsils. Although only about 20 per cent. of asthma cases give positive reactions to protein tests, these should be performed as a routine for purposes of classification. Deep breathing exercises are essential in treatment, and sodium iodide intravenously, at half daily and then once or twice a week, affords distinct relief to cough and expectoration. Diathermy treatment two or three times a week for half an hour is one of the best palliative measures, and hypodermic injections of 1/2 to 1 c.c.m. of a 10 per cent. pepsine solution give more or less permanent relief. Diet should be regulated upon the data derived from the stool examination, cutting down the protein intake where there is much albuminuria. Injections of histamine and sugar in carbohydrate putrefaction and eliminating starch and sugar in carbohydrate fermentation. Injections of histamine to immunize against results, but at present the cases are insufficient in number to warrant a definite statement. Small doses of adrenalin treatment with a view to immunizing against the various pollens should be commenced three months before the attack being frequently due to insistent immunization. J. P. D. RIVERS (*ibid.*, p. 750) calls attention to the psychology of hay fever, and urges the importance of combining medical and surgical treatment of any local conditions which will afford symptomatic relief with the intelligent use of psychotherapy.

158.

### The Digestion of Tablets and Pills.

WINSLOW (*Ugeskrift for Læger*, July 12th, 1933, p. 425) points out that at present little is known as to the rate at which a tablet containing reduced iron and not breaking up within an hour of swallowing is practically useless, and Easton's syrup tablets, which do not decompose within a day or more, are not only useless but may be dangerous, for if they are taken over a considerable period by constipated patients deposits of erythema may form in the intestinal tract. The author has carried out tests with pills and tablets of reduced iron and of other drugs such as dissolvin and digalen. The pills and tablets were put in water at room temperature and the time taken to dissolve them was noted. The preparations tested were made by several Danish chemists and one foreign firm of manufacturing chemists. The pill containing reduced iron and sold by this foreign firm was quite intact after three hours' soaking in water, whereas the home-made pills dissolved in half an hour to two hours. The tablets of Easton's syrup solid by the foreign firm still showed a hard nucleus after twenty-four hours. It is doubtful

and extended the view that the nuclei of all atoms are built of protons of mass nearly 1 and of electrons. The nucleus of a heavy atom, he said, is undoubtedly a very complicated system, and in a sense a world of its own, little, if at all, influenced by the ordinary physical and chemical agencies at our command. When we consider the mass of a nucleus compared with its volume it seems certain that its density is many billions of times that of our heaviest element. Yet, if we could form a magnified picture of the nucleus, we should expect that it would show a discontinuous structure, occupied but not filled by the minute building units, the protons and electrons, in ceaseless rapid motion controlled by their mutual forces.

#### *Energy Relations involved in the Formation and Disintegration of Atomic Nuclei.*

For example, it is well known that the total evolution of energy during the complete disintegration of one gram of radium is many millions of times greater than in the complete combustion of an equal weight of coal. It is known that this energy is initially mostly emitted in the kinetic form of swift  $\alpha$  and  $\beta$  particles, and the energy of motion of these bodies is ultimately converted into heat when they are stopped by matter. Since it is believed that the radio-active elements are analogous in structure to the ordinary inactive elements the idea naturally arose that the atoms of all the elements contained a similar concentration of energy, which would be available for use if only some simple method could be discovered of promoting and controlling their disintegration. This possibility of obtaining new and cheap sources of energy for practical purposes was naturally an alluring prospect to the lay and scientific man alike. It is quite true that, if we were able to hasten the radio-active processes in uranium and thorium so that the whole cycle of their disintegration could be confined to a few days instead of being spread over thousands of millions of years, these elements would provide very convenient sources of energy on a sufficient scale to be of considerable practical importance. Unfortunately, although many experiments have been tried, there is no evidence that the rate of disintegration of these elements can be altered in the slightest degree by the most powerful laboratory agencies. With increase in our knowledge of atomic structure there has been a gradual change of our point of view on this important question, and there is by no means the same certainty to-day as a decade ago that the atoms of an element contain hidden stores of energy.

It is possible by means of electron bombardment or by appropriate radiation to excite an atom in such a way that one of its superficial electrons is displaced from its ordinary stable position to another temporarily stable position further removed from the nucleus. This electron in course of time falls back into its old position, and its potential energy is converted into radiation in the process. There is some reason for believing that the electron has a definite average life in the displaced position, and that the chance of its return to its original position is governed by the laws of probability. In some respects an "excited" atom of this kind is thus analogous to a radio-active atom, but of course the energy released in the disintegration of a nucleus is of an entirely different order of magnitude from the energy released by return of the electron in the excited atom. It may be that the elements, uranium and thorium, represent the sole survivors in the earth to-day of types of elements that were common in the long distant ages, when the atoms now composing the earth were in course of formation. A fraction of the atoms of uranium and thorium formed at the time has survived over the long interval on account of their very slow rate of transformation. It is thus possible to regard these atoms as having not yet completed the cycle of changes which the ordinary atoms have long since passed through, and that the atoms are still in the "excited" state where the nuclear units have not yet arranged themselves in positions of ultimate equilibrium, but still have a surplus of energy which can only be released in the form of the characteristic radiation from active matter. On such a view, the presence of a store of energy ready for release is not a property of all atoms, but only of a special class of atoms like the radio-

active atoms which have not yet reached the final state for equilibrium.

Calculation shows that the energy released in the formation of one pound of helium gas is equivalent to the energy emitted in the complete combustion of about eight thousand tons of pure carbon. It has been suggested that it is mainly to this source of energy that we must look to maintain the heat emission of the sun and hot stars over long periods of time. Calculations of the loss of heat from the sun show that this synthesis of helium need only take place slowly in order to maintain the present rate of radiation for periods of the order of one thousand million years. It must be acknowledged that these arguments are somewhat speculative in character, for no certain experimental evidence has yet been obtained that helium can be formed from hydrogen.

#### *POSSIBILITIES OF THE FUTURE.*

In the short time at my disposal it has been impossible for me, even if I had the knowledge, to refer to the great advances made during the period under consideration in all branches of pure and applied science. I am well aware that in some departments the progress made may justly compare with that of my own subject. In these great additions to our knowledge of the structure of matter every civilized nation has taken an active part, but we may be justly proud that this country has made many fundamental contributions. With this country I must properly include our Dominions overseas, for they have not been behind-hand in their contributions to this new knowledge. It is, I am sure, a matter of pride to this country that the scientific men of our Dominions have been responsible for some of the most fundamental discoveries of this epoch, particularly in radio-activity.

This tide of advance was continuous from 1896, but there was an inevitable slackening during the war. It is a matter of good omen that, in the last few years, the old rate of progress has not only been maintained but even intensified, and there appears to be no obvious sign that this period of great advances has come to an end. There has never been a time when the enthusiasm of the scientific workers was greater, or when there was a more hopeful feeling that great advances were imminent.

#### *The Scientific Imagination.*

In watching the rapidity of this tide of advance in physics I have become more and more impressed by the power of the scientific method of extending our knowledge of Nature. Experiment, directed by the disciplined imagination either of an individual, or better still, of a group of individuals of varied mental outlook, is able to achieve results which far transcend the imagination alone of the greatest natural philosopher. Experiment without imagination, or imagination without recourse to experiment, can accomplish little, but, for effective progress, a happy blend of these two powers is necessary. The unknown appears as a dense mist before the eyes of men. In penetrating this obscurity we cannot invoke the aid of supermen, but must depend on the combined efforts of a number of adequately trained ordinary men of scientific imagination. Each in his own special field of inquiry is enabled by the scientific method to penetrate a short distance, and his work reacts upon and influences the whole body of other workers. From time to time there arises an illuminating conception, based on accumulated knowledge, which lights up a large region and shows the connexion between these individual efforts, so that a general advance follows. The attack begins anew on a wider front, and often with improved technical weapons.

#### *Conditions Necessary for Progress.*

The intellectual interest due to the rapid growth of science to-day cannot fail to act as a stimulus to young men to join in scientific investigation. In every branch of science there are numerous problems of fundamental interest and importance which await solution. We may confidently predict an accelerated rate of progress of scientific discovery, beneficial to mankind certainly in a material but possibly even more so in an intellectual sense.

[illegible]

On the other hand, there is good evidence that the native practitioners perform a useful service in the villages, more especially on the medical side of practice and in the treatment of ordinary diseases, although in the absence of adequate scientific training they must often have the character of "medicine men."

#### *The Demands of the Indigenous Practitioners.*

From these considerations it would seem that the ground is clear either for the introduction of the European system or the resuscitation of the indigenous system, whichever may be deemed preferable. Doubtless there exists among the more educated Ayurvedists a natural and praiseworthy desire to retain their national systems, and it is, moreover, probable that European scientists are inclined to ignore the force of the religious element. That there is a strong religious feeling intermingled with the purely practical part of the question can hardly be doubted, and it becomes evident in such statements as the following:

"Every system of Hindu thought is at once philosophy, science and religion, all in one and one in all."

"Ayurveda will never consent to lose its characteristic of thinking in terms of its own peculiar religious philosophy of Satwa, Rajas and Tamas."

To wound this feeling and unnecessarily run counter to it is undesirable and would be bad policy, and for this reason alone the Government would be well advised to give such temporary support to the systems as will prevent their entire decay and enable them to continue their present services, in face of the impossibility of immediately replacing them by anything better.

The demand of the Ayurvedists is that their system shall be resuscitated and recognized by the States as constituting a sound basis of medical education and practice. The demand can be fairly considered only by those who possess a competent knowledge of Ayurveda, and the report purports to furnish the means of acquiring this knowledge. It is, however, stated that much misunderstanding and unfair criticism have resulted in the past through the mis-translation of scientific terms by European writers on the subject of Ayurveda. The following account is, therefore, based solely on the information contained in the report, and is an attempt at an unbiased interpretation.

It will be admitted on all hands that Ayurveda was a great science in its day; but it does not follow, as the report, in dealing with the Unani system, seems to imply, that what was useful centuries ago is necessarily profitably retained at the present time. It is asked:

"Can Europe forget the time when European students derived instruction in their medical colleges for centuries together from the self-same Unani books which they were then hugging to their bosoms and which in Arabic find a place to-day in the syllabus of our medical colleges? . . . All evidence points to the allopathic system being the transformed Unani system. Can any sensible man, in the circumstances, declare the Unani system to be crude and unscientific?"

The reply is that it may well be so according to modern standards. The three systems—Ayurveda, Siddha, and Unani—have much in common and, so far as description is concerned, what is stated with regard to Ayurveda, the most important of the three, may be held to apply to the other two.

#### *General Principles of Ayurveda.*

Ayurveda means, literally, the science of Ayus, a name denoting the momentum of vital activities, upon which the duration of life, or the expectation of life, depends. The Ayus varies in different individuals according to their inherited constitution, and is modified by internal and environmental conditions. On its practical side Ayurveda lays down rules for adjusting our circumstances to our constitutions, in order that our Ayus may suffer no diminution and life may have its normal duration.

Behind material things there exists an All-Intelligence, Soul or Spirit (Purushu), from which all matter emanates and which constitutes the generating force of every phenomenal activity. Everything in Nature, including mind, is matter—the emanation or "expression" or "function" of the spirit. But matter is not to be conceived of in the

abstract as dead, but always as endowed with various potential activities, such as vibrational energy, taste-energy, smell-energy; and it is of two kinds, Bhuta and Guna, differing in the character of their inherent energies. Bhuta-matter is endowed with energies that reveal themselves in the several physical states, and it exists in five forms—Prithvi (solid), Ap (liquid), Vayu (gas), Thejas (radiant matter), and Akash (ether). Guna-matter appears to be a more direct emanation of Spirit (Purushu), and is, in fact, the substance into which primal matter differentiated itself when the universe first came into manifestation. It exists in three forms—Rajas, Satwa, and Tamas—corresponding to the Trinity of the Spirit, and it imparts this threefold nature, as a fundamental characteristic, to every manifested existence in the phenomenal universe. Combined with and operating upon Bhuta-matter it constitutes the living body, which is itself permeated with the Soul, forming the living being. All things are thus constituted; all are living beings, and the distinction between animate and inanimate objects does not exist; but inasmuch as the Soul is independent, absolute, and uninfluenced by the activities of the body, it may be disregarded in the study of bodily processes. Although the constitution of all things is identical, the degree of organization—the position in the evolutionary scale—varies, the mode in which Gunas and Bhasas react and interact on one another giving to each being its particular individuality, Ego, or Jiva, the human Jiva being that Guna-Bhasa combination which is peculiar to man.

The specific energies residing in Bhuta-matter tend, as before stated, to the manifestation of physical states (liquid, solid), and although they may, presumably, modify one another when acting in combination, the correlation of energies is not their function. On the other hand, correlation may be considered as the characteristic function of the three Gunas. When they are in equilibrium there is no revelation; when the equilibrium is disturbed the manifest universe appears, and all things result from their peculiar arrangement and combination. In general terms the energy of Rajas may be said to be creative or dynamic; that of Satwa, sustentative or transformative; that of Tamas, conserving or static.

When acting on Bhuta-matter the threefold influence, before referred to, of the Gunas becomes evident, and three substances result—Vata, Pitta, and Kapha—representing the primal constituents of the living body. The relation of these three substances to the several forms of Guna- and Bhuta-matter is that Vata contains Akash (ether) and Vahu (gas), and is under the predominant influence of Rajas; Pitta contains Thejas (radiant matter), and is under the predominant influence of Satwa; and Kapha contains Ap (liquid) and Prithvi (solid), and is under the predominant influence of Tamas.

#### *Ayurvedic Conceptions of Metabolism.*

From the foregoing details regarding the energies inherent in the various forms of matter it is possible to deduce the physiological relations of the three substances or Dhatus, as they are called. Vata is concerned with those physical and mental processes which are creative or dynamic in nature; hence its presence is to be inferred in such mental phenomena as enthusiasm, concentration, etc., and in such physical phenomena as respiration, circulation, voluntary action, excretion, and in the activities of the nervous system as a whole. Pitta is concerned with sustentative or transformative processes; hence its presence is to be inferred in such mental phenomena as intellection and clear conception, and in such physical phenomena as digestion, assimilation, heat production, the activities of the nutritional system as a whole, secretory activities of all kinds, and metabolism generally. Kapha is concerned with processes that are conserving or static in nature; hence its presence is to be inferred in such mental phenomena as courage, forbearance, etc., and in such physical phenomena as promotion of bodily strength, the integration of the structural elements of the body into stable structures, the smooth working of joints, and the activities of the skeletal system as a whole. It is also concerned in thermo-regulation, the tissues being liable to be consumed by the "internal fires of Pitta" unless protected by the "waters of Kapha."

A British Medical Association Lecture

SOME PITFALLS IN THE DIAGNOSIS AND TREATMENT OF PULMONARY TUBERCULOSIS.

OLIVE RIVIERE, M.D. LOND., F.R.C.P.,  
PHYSICIAN, CITY OF LONDON HOSPITAL FOR DISEASES OF THE HEART  
AND LUNGS, AND SHAWHILL CHURCH'S HOSPITAL.

HAVING been offered the wide subject-matter of pulmonary tuberculosis for my lecture, it has seemed to me that the best I can do is to concentrate on certain matters which are, in my opinion, of primary practical importance. These, almost of necessity, come within the two headings "Diagnosis" and "Treatment," and we naturally begin with the former. I do not propose to waste time over ordinary points of diagnosis, important though these may be; I am anxious instead to face some special pitfalls which await us, not in the ordinary straightforward case, but in the exceptional case which—paradoxical as it seems—is really the commonest one to meet us in private practice. Most serious among these is the case which develops and progresses without physical signs, or without such physical signs as any self-respecting case of pulmonary tuberculosis ought to present—in other words, the case which is not a case of apical phthisis. Let us start with this.

It has been my good fortune to be physician to a large children's hospital, and, taking always a great interest in lung disease, to have had much experience of pulmonary tuberculosis as it affects the child. In early life, as you know, a primary lung focus gives rise to secondary infection of glands, and from these the lung is again infected in a case where disease progresses further. Nearly always immunity has by this time reached a high level, the lung infection is a slight one and confined to the neighbourhood of the roots and larger bronchi, and life is no wise threatened. Here and there we find a case where from spreads onwards, showing itself in the radiogram first as a larger area of lung, till, in late stages, it appears to reach out to the periphery. This is the condition, whether slight or serious, which we speak of as *hilus tuberculosis*, or *glandular and hilus tuberculosis*. However the spread is accomplished, it has begun deep in the lung, and has only at a late stage reached the periphery over which our stethoscope is hovering.

What, then, is the clinical aspect of tuberculosis in childhood? A child is brought to you with symptoms suggestive of tuberculosis—that do you find on examination? If you examine carefully you will find in practically all cases that the percussion note is slightly against the right lung both front and back, and that there is a right paravertebral dullness disposed as a semicircular area against the spine. You may also find an increase of pericardial dullness, blowing breath sounds over the upper vertebral spaces, and various other signs; but what you do not find (except in advanced stages of disease) is the presence of crepitations. Indeed, the stethoscope may tell you nothing at all, and this is, in my experience, the rule. Not if you have learnt wisdom from experience. No, having found the signs referred to above you may say with confidence, "This is a case of glandular or hilus tuberculosis," but you cannot tell in the least from physical signs whether the disease is of no account and healing or healed, or whether both lungs are half filled with active bronchopneumonic tubercle. The physical signs are the same or similar in both cases, and the really vital part of the diagnosis has to be deduced from symptoms and the history before the Hastings Division of the British Medical Association.

And here let me digress for a moment to say a word about that radiogram in childhood. In infancy and up to the age of 5 years or so the lung picture is pretty clean in the healthy child, and a superadded tuberculosis or bronchopneumonia or suchlike is very clear and apparent. But the radiogram of a child of school age—especially from 8 or 9 years upward—is already greatly shadowed with past sin, whether in the shape of silicosis, or of healed tubercle, and other chest infections, and it requires a lot of experience to interpret it correctly in a case of doubtful tuberculosis. In slight and recoverable disease, such as we have mentioned, often it can only be said that the radiogram is "consistent" with a slight active tuberculous lesion. Fortunately in the more serious cases the radiogram is reliable—really active tubercle round the hilus throws shadows which are hardly mistakable, and the x rays are very valuable in following the course of the disease.

Deep Lung Tuberculosis in the Adult.

Now I have lingered so long over hilus tuberculosis of the child because it illustrates what I have to say of the adult. The child is father to the man, and no small proportion of the tuberculous outbreaks of early adult life (and even in later years) are a spread from these deep areas round the roots of the lungs. Hilus tuberculosis, which is the rule in the child, is also by no means uncommon in the adult. Just as in the child, there is nothing discoverable to the stethoscope, and, as the stethoscope is still the instrument of choice with most physicians, nothing may be found in these cases to suggest a diagnosis of pulmonary disease. What happens to an adult who develops deep-seated *hilus tuberculosis*? Let us hope, for his sake, that he coughs, for otherwise his chances of recognition are small. Unfortunately it is by no means uncommon for such cases to cough but little in the earlier stages, or to take small but of toxic origin. Many of these cases, in my experience, have been given rest cures as frank neuroasthenia at the outset, and if a careful temperature chart were taken in the nursing home and duly studied this might, indeed, be a step of value. But often in these cases the temperature is not such as to lead to suspicion, and having received the neuroasthenic label they are very apt to go further on this journey. It has been my experience of recent years to be asked by a distinguished neurologist to exclude tuberculosis in cases of neuroasthenia, so the lesson of these cases has evidently been learnt in high places.

How can we escape the pitfall of deep-seated or hilus tuberculosis simulating other conditions, and especially neuroasthenia? First, and especially, by recognizing its possibility, and using means to exclude or confirm it. Among these are a careful temperature chart, x rays, which help but do not always decide the matter, and the search for certain physical signs, among which narrowing of the general resonance (Kronig's) on both sides—for disease is generally double—is important evidence. Suspicion is the first stage on the road to diagnosis, and full recognition of the fact that a lung may be full of deep disease without giving any definite physical signs at the surface. Recognize frankly that your stethoscope may be as useless in these cases as if you applied it to the wall of the patient's house! Develop your powers of percussion, and do not despise the help of the radiologist. In these days, when the value of artificial pneumothorax is beginning to gain recognition in this country, it is quite common to be presented with a case in which the stethoscope finds moist crepitations over the whole of one side, and the other side appears to be entirely clear. In such cases when a radiogram is taken it may often be found that disease is active and advanced on both sides, although the stethoscope could only find it on one. The spread on one side is only a bit more advanced than the other, and has reached the surface; presently, in weeks or months, crepitations will appear on the apparently clear side and rapidly spread over the surface. These cases, in fact, present a somewhat different aspect of the same diagnostic [3273]

technique, etc. What they really need is an altered scientific outlook; they need to understand the difference between metaphysical and positive knowledge, between the study of facts through the coloured glass of theological dogma and their study in the plain daylight of science. The Madras Government is apparently at the parting of the ways. It will be interesting to see whether it decides to set things moving in the path of progress by the encouragement of European scientists, or pushes the country back into the old metaphysical rut.

## HOSPITAL CONTRIBUTORY SCHEMES.

AN ANALYSIS BY THE VOLUNTARY HOSPITALS COMMISSION.

At the request of a conference of representatives of local voluntary hospital committees, held in July, 1922, the Voluntary Hospitals Commission undertook to issue a questionnaire on the methods pursued in various areas to obtain contributions, and to circulate to the local committees a summary of the information received. Replies were furnished in regard to 73 contributory schemes affecting 102 hospitals, and a statement summarizing the particulars given has now been circulated for the information of local committees and the hospitals in their areas.<sup>1</sup>

This summary is in narrative form, with little if any comment. It comprises sections dealing respectively with the machinery for working a contributory scheme, methods of collection, amount and remittance of contributions, the cost of collection, allocation of contributions, privileges of contributors, effect of schemes upon patients' payments, representation of contributors, methods of publicity, and factors influencing success.

### *Machinery of Contributory Schemes.*

Local circumstances largely determine the machinery for working a particular contributory scheme. Whether the scheme will be worked for one institution, or in common for several, depends on the relations between the hospitals in the area; some are accustomed to acting alone, others to co-operating with neighbouring institutions. Another important factor is the nature and extent of local charitable organizations. Even more important is the character of the area served by the hospital—that is, whether the area is mainly rural or mainly industrial; and, if the latter, whether it is covered by a few highly organized industries. The variety of local conditions is reflected in the variety of methods that have been adopted for working contributory schemes; these range from a scheme worked by a single hospital through its own secretary and treasurer, to one worked by a highly organized hospital council on which there are representatives of all the hospitals in the area, of the city corporation, and of various trade associations and public bodies. Between these two extremes many kinds of organization are found.

### *Methods of Collection.*

Almost every scheme known to the Commission relies for its contributions mainly upon deductions from wages, with the consent of the wage-earners and the active co-operation of their employers. An area containing a few highly organized industries offers the best field for this procedure. As a rule the weekly deduction is made by pay clerks at the works, and sometimes the employers add a contribution of their own. This is the usual and principal method of collection. But there are in addition other avenues through which funds are collected, and many schemes use them concurrently with the weekly deductions from wages; thus the residential population may be canvassed by systematic house-to-house collection, or by applications through the post. In many areas valuable help is given by trade unions and employers' associations. Collection in a rural area presents much greater difficulty, and even more difficult is the gathering in of regular contributions from the "self-employer."

### *Amount and Allocation of Contributions.*

Many schemes have fixed twopence a week as the sum

payable by each contributor. Others, however, permit the amount to vary between one penny and threepence, in some cases at the choice of the contributor. Sometimes the larger contribution covers privileges for the employee and his family, while the minimum sum would cover only the employee himself. Here and there the amount of contribution varies with the wages earned, upon a graded scale. In most schemes the services of a voluntary collector are available. Where it is shown separately in the accounts the cost of collection has not been observed to exceed 3 per cent. of the amount collected.

In the simplest forms of contributory schemes the whole of the contributions are paid to the hospital and are allocated to meet maintenance expenditure; they are rarely applied to capital purposes. In a number of schemes the hospital does not take the whole of the amount subscribed, but some allocation is made to other services, a percentage going, for example, to convalescent homes, nursing associations, and in one instance to dental services.

### *Privileges for Contributors.*

Priority of admission for contributors, or free maintenance or treatment, as an inducement to attract members, is perhaps the most important and the most difficult feature in framing a contributory scheme. Many hospitals feel the necessity of offering some special inducement in return for the assured income obtained from regular contributors. On the other hand, it is generally recognized, and indeed often required by trusts and endowments, that the first claim on a voluntary hospital's accommodation and resources should be that of the necessitous poor. Moreover, the governing condition in the admission of patients should obviously be the urgency of the medical or surgical need of the case. With these considerations in mind most hospital authorities have been careful to avoid holding out any inducement which would bind them in a contractual obligation. But in one or two instances the hospital authorities have taken the risk of guaranteeing to all their contributors certain definite benefits, such as free maintenance or immediate admission and treatment. Some schemes, without pledging themselves to the admission and free maintenance of contributors, provide as an inducement certain special benefits and facilities not available to non-contributors. A very common form of inducement is the simple practice whereby contributors when admitted to hospital are maintained and treated free of charge without being asked to make a donation. In regard to eight of the contributory schemes, the promoters state that no inducement or privilege is accorded to the contributors, the hospital authorities relying, and with success, on the charitable instincts of their contributors, the sole criterion of admission being the urgency of the case. Thus, while a very small minority of schemes attempt to guarantee something in the nature of an insurance benefit, most of them rely upon the charitable instincts of the public and maintain the principle that the necessitous poor and the medically urgent cases must have the first call upon the resources of the hospital. Subject to that, the contributors in practice get facilities for admission and are not usually asked to make any further donation to the hospital. Sometimes additional privileges are provided; among these, facilities for convalescent treatment are very popular. It is noted that of all the schemes examined only four indicated that payments by patients have diminished as a result of the operation of a contributory scheme.

The representation of workpeople contributing upon the governing bodies of hospitals is recognized as an important element in contributory schemes, and very few make no provision for such representation. The manner of election and the basis of representation vary much, more particularly in relation to the machinery adopted for working the scheme. The bodies on which the workpeople's representatives serve also vary; in some places they have seats only on the board of management, in others they are eligible for election to the committee of management and the house committee. The contributors may have representation upon a purely financial basis, the contribution of a given sum entitling to the nomination of a governor or member of the managing committee; or the contributors as a body may be entitled to a fixed number of representatives; or, again, the

<sup>1</sup> Voluntary Hospitals Commission. Ministry of Health, 1923. V.H. Cm. 10. To be purchased through any bookseller or directly from H.M. Stationery Office. Price 3d. net.

Said Hermann Weber once in days gone by, "I would not willingly undertake to treat a case of phthisis without the help of exercise," to which Remond reported, "I would not willingly undertake to treat a case of phthisis without rest, keeping exercise as an exceptional measure." Whereupon Detweiler settled the dispute with the remark, "The truth lies really in the proper application of both measures to suitable cases, though rest is, to my seeing, the primary factor." The key to success lay, he opined, in the "correct dosing of rest and exercise," and that is much where the matter remains to-day.

Theory and experiment have, however, come to the assistance of empiricism, and have provided a working basis—the blessed word "auto-inoculation" has filled our minds with peace, and our mouths with a plausible explanation of many perplexing problems. Albreuth Wright revealed to us the great game of "antigen" and "antibody," he showed us how the resisting power of the body to chronic infections depends on a proper balance between them, how a suitable supply of bacterial products (antigen) is needed to produce an immunizing response (production of antibody), and how excessive and uncontrolled dosage may overcome antibody formation, with the result that symptoms appear and disease spreads; how, further, once the balance is disturbed it can only be recovered by control of the bacterial toxins let loose (control of auto-inoculation) by rest and similar measures. At a later stage there may be brought about a gradual training of the body to resist larger and larger doses (tolerance), while at the same time "immune reactions" are developed to every adequate exposure of exercise. For auto-inoculation may follow upon "all active and passive movements which affect the focus of infection, and upon all vascular changes which activate the lymph stream in such a focus." Here is our working hypothesis, and it has been to the work of Paterson and Toman in particular that we owe its full application to the case of pulmonary tuberculosis. The role of rest and exercise in its treatment resolves itself, in the words of Paterson, into two aims:

1. "Control of auto-inoculations when the protective substances are unable to deal with them."
2. "The artificial inducement of auto-inoculation adjusted to the resisting power of the protective substances."

It is, of course, the former alone which applies to the newly discovered or still half-diagnosed case—it is a case with symptoms, and these are evidence of a breakdown of immunity which only rest can straighten.

*The Rationale of Rest.*

The main reason for rest is fever—it provides "control of auto-inoculations when the protective substances are unable to deal with them," and enables us to reach generally a fresh formation of antibodies. Not only does uncontrolled dosage with antigen defeat the formation of antibodies, it also acts deleteriously by "activating" all tuberculosis lesions within reach of the blood stream. Just as an overdose of the tuberculin "will let loose" "focal reactions" in company with a "general" or febrile reaction, so is fever in tuberculosis accompanied by a disastrous flooding of the tuberculous areas with blood deficient in antibodies, and a further washing out of toxins and waste products into the blood stream. This leads to further fever, and thus a vicious circle is kept up, which can be broken only by rest, continued and sufficient.

But a further task awaits the tissues in the erection of "fortifications" round the areas of disease with a view to their encapsulation, and this, again, requires a period of rest after all fever has subsided. It has been shown that the infection of a chemical irritant into the lung excites the formation of inflammatory zones whose nature varies with the concentration of the irritant—thus a central necrosis, then a fibrous layer, next serious inflammation, and lastly, around all, a zone of proliferating fibrous tissue. A similar process occurs in response to the toxins of the tubercle bacillus. When the parts are at rest, a zone of fibrous tissue will form at the spot of "optimum irritation," and good encapsulation ensue. If much movement is allowed

there will be no fixed optimum, and a wider spread of less well developed fibrous tissue instead of a limiting capsule. In addition to this it may be further expected that immunization acts by reducing the lymph flow to the diseased area and thereby diminishing the introduction of nutriment and the extraction of waste products till the growth of bacilli and the formation of toxins cease.

In connection with this argument, and perhaps with those to come, it is but fair to point out that immunization of the lung acts as a two-edged sword in its application to tuberculosis. While collapse and immobility of the organ are, on the whole, unfavourable to the development of tuberculosis, there is a phase of expansion and movement between this and complete activity which is very favourable to the development of tubercle. This shows itself in the more rapid growth of tubercles in the apical regions of the lungs than in the more greatly aerated basal areas in cases of military tuberculosis where we know all tubercles are of equal age.

As a matter of experience it appears that the control of auto-inoculation is of vastly more importance than any accidents of extension or movement in portions of lung tissue, and it is primarily to this that our therapeutic rest should be applied.

Nevertheless, on the mechanical side there seem to be two other arguments in favour of rest while disease is still active. One is the increased movement and extension, the result of exercise of an organ doomed of necessity to some amount of this. It must be difficult enough for a wound or inflammatory area to heal under the peculiar conditions of elastic tension and continual movement always present in the lung. If these are increased by talking and exercise it must necessarily make the process still more difficult. The other point is the peculiarity of the pulmonary blood supply which puts it at the mercy of the systemic circulation. Provided with but little vasomotor control, with no power of stopcock action such as obtains in the greater portion of diseased areas unless by mechanical blockage, protection, the lungs are doomed to pass through, with no exception of diseased areas, the systemic circulation sets in whatever mass of blood the systemic circulation sets in motion. Especially does muscular activity increase this flushing his inflamed lung areas with blood. This may not fluctuate, and a pattern moving about is all the time fluctuating (the patient may have developed "tolerance"), but even apart from this such intermittent flushings are not the best treatment of tuberculous areas as long as these are active. This, in my opinion, is one of the pitfalls in treatment: the belief, commonly held, that exercise is harmful so long as it does not cause fever—that is, so long as there is "tolerance."

Now it is especially where large areas of exudative inflammation exist—that is, in cases of fairly acute type—that flushing and movement very certainly do harm. We are familiar with the softening and discharging of caseous germinal glands where heat and unresisting movements are applied. In the neck this may shorten the cure, but in the lung it means "cavitation," a disastrous method of removing diseased material since the tissues kept at tension cannot close the breach. Hence for all cases of active pneumonia or exudation which may become caseous and soften, prolonged rest is surely indicated. But it must also be remembered that in every tuberculous lung such areas on a smaller scale are present; Detweiler has compared it to a mulberry tree on which are found at the same time flowers, and fruit both green, red, and black together—in the same organ. This mixed process must be borne in mind in treatment. But what must also be specially kept in view in relation to this is the fact that absence of fever is not evidence that disease has become inactive. The physical signs clearly indicate that activity is still present, and only slowly abating, for months after rest in bed has reduced fever and symptoms to a minimum. Such patients can be got up and tolerance established, but as long as disease is active, if it is of any extent or seriousness (and it needs much skill to know what cases are not) there is no

## A CRITICAL SURVEY.

PHYSICIAN, BROOKTON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST; PHYSICIAN TO OUT-PATIENTS, ST. MARY'S HOSPITAL.

that the results upon which we are basing our judgment of the results of the lesson are not a positive result is an indication of active tuberculous lesion in the body, and that a negative result is a reliable indication, with a few rare exceptions to which we shall refer later, of the absence of such lesion."

from non-tuberculous diseases were taken as negative controls. Three gave a positive result. Of these 3, in one definite evidence of earyngitis was subsequently discovered, in another on more or less certain examination it was impossible, while in the third no evidence of ulceration could be discovered. Of the remaining 700 cases some 220 gave a positive result and some 480 gave a negative. These were doubtless clinical, so that no definite conclusion could be drawn from them. All that could be said at the time was without a doubt that there seemed to be of the order of 50 per cent of the cases corresponding between the clinical condition on the one hand and the subsequent histological result on the other. The subsequent histological result of 50 of the cases were

clinically, so that no definite conclusion could be drawn from them. It might be said that the same criticism might later be applied to the researches of the other two groups of respondents between the clinical condition on the one hand and the negative or positive result on the other.

The subsequent history of 50 of the cases which were

Variability of Results due to Employment of Different Antigens.

There can, we think, be little doubt that the variability of the results obtained can be partially explained by the variety of the antigens used.

Millett<sup>1</sup> has classified the antigens used into four main groups:

This article does not pretend to be a complete review of all the literature upon the subject, but merely aims at indicating the conclusions we have arrived at after a perusal of it, so that no attempt will be made to put the thing like a complete list of all the most interesting results. We shall be content here to point out our own work in connection with reference to the work of other investigators.

It would appear to us that generally the most reliable results have been obtained with antigens belonging to this group. It is antigen of this type—that is to say, a dilute emulsion of living tubercle bacilli—that we have used in our investigation. It is especially in relation to their specificity that antigens of this type appear to be superior. Dudgeon, Meek, and Weir, using an antigen belonging to this group, obtained 86 positive results out of 102 “definitive cases of pulmonary tuberculosis.” But of the 16 cases that gave a negative result, in 4 tubercle bacilli were said to have been present in the sputum two months previously, but were not present at the time the test was performed, and no symptoms or physical signs of pulmonary disease were present. One was a case of old tuberculous leprosy, one was diagnosed by a febrile reaction only. In 2 physical signs and symptoms of pulmonary disease were present, but no tubercle bacilli were present in the sputum. One was in a moribund condition. In 7 tubercle bacilli were present in the sputum. So that excluding the case that was moribund, only 7 could be said definitely to be suffering from pulmonary tuberculosis at the time the test was performed. McIntosh and Eldes, using an emulsion of living tubercle bacilli as antigen, obtained 76 per cent. of positive

consideration, that no one at present unprotected or insufficiently protected need have the least fear of the disease if only he will undergo vaccination or revaccination.

## Ireland.

### MEDICAL REPRESENTATIVES IN THE DAIL.

Of five medical representatives who sat in the last Dail three have been re-elected in the last election—namely, Sir James Craig, M.D., Dr. Richard Hayes, and Dr. Myles Keogh. Sir James Craig was one of the three representatives elected, without a contest, for Dublin University. Dr. Hayes was elected at the head of the poll for Limerick, and Dr. Keogh was elected for South Dublin. These three members are keen medical reformers. Sir James Craig and Dr. Richard Hayes have outlined, from time to time, important schemes of medical reform, and in this way have done a great deal to enlighten the public with regard to the urgent necessity there is in Ireland for far-reaching measures of medical legislation. Amongst the anti-treaty party elected there are no fewer than five members of the medical profession, two of whom are dispensary doctors. These members include Dr. Kathleen Lynn, who has done a great deal of medical work amongst the poor in Dublin. It is, however, understood that she and her colleagues will not sit in the present Dail, and therefore cannot help within that body in the formulation of any medical schemes. It is to be regretted also that Sir James Craig is the only member of the profession amongst the six representatives elected for Dublin University and the National University. The other five university members are members of the professorial staff, and it is believed they are all quite alive to the pressing necessity there is to bring the Free State abreast, in medical affairs, with other countries in Western Europe and America. The Labour party has not come back to the Dail as strong as was expected. The Labour party, more than any other organized body, took the keenest interest in medical legislation in the last Dail.

### SALARIES OF TUBERCULOSIS OFFICERS.

At a recent meeting of the Kildare County Council a letter from the Local Government Department was read relative to the proposal to increase the salary of Dr. J. P. Daly, tuberculosis officer, to £700 per annum, rising by annual increments of £20 to £900 per annum. The letter pointed out that Dr. Daly's present remuneration of £500 compared favourably with the salaries of the great majority of the tuberculosis officers in other counties, some of whom were responsible for the supervision of local institutions. Moreover, there had been but little development of the county tuberculosis scheme, which was still in an imperfect condition, without a central tuberculosis dispensary or suitable provision for the accommodation of advanced cases. The Ministry considered that the character of the scheme would not in any case justify the proposed increase of salary, which seemed to be framed on an excessive scale, and having regard to the existing conditions no adequate case had been made out at present for revision of the tuberculosis officer's remuneration of £400 yearly salary and £150 bonus. The Ministry suggested that it would be desirable to defer further consideration of the matter pending the carrying out by the council of the necessary extension of the county scheme, when a further proposal involving a reasonable adjustment of Dr. Daly's basic salary might be submitted. Having considered this letter, the council unanimously decided to allow the full civil service bonus.

### HEALTH OF BELFAST.

Dr. Baillie, superintendent medical officer of health for the city of Belfast, has presented his report for the year 1922. It is a well printed volume of 86 pages, with thirty-four tables of statistics, numerous minor tables, and a good index.

No census was taken in 1921, so that the population of 425,000 is an estimate; and estimates of population, as is pointed out, become more unreliable with every year from

an actual census. The birth rate calculated on the estimate was 25.1, a decrease of 1.2 from that of the preceding year; and the death rate was 14.8, a very satisfactory figure when comparison is made with the rates of twenty years ago, but still an increase of 0.4 on 1921. There was a reduction of 0.8 per 1,000 of population in the death rate from zymotic diseases (0.6 per 1,000 of population in 1922, and 1.4 in 1921), and an increase of 0.4 in deaths from chest affections. Deaths of children under one year old per 1,000 births were 94, which is 21 per 1,000 less than that for 1921.

The centres established in 1917 under the maternity and child welfare schemes are working satisfactorily, and are well attended by expectant mothers; 2,746 medical examinations of babies were made. The scheme for the medical inspection of school children, which had been hung up by the war and post-war difficulties, was finally adopted in October, 1922, approved by the Ministry of Home Affairs, and put into operation. The town has been clear of small-pox now for two years. Scarlet fever, diphtheria, whooping-cough, and measles still figure as chief executors in the "massacre of the innocents."

Excellent reports are included from the heads of departments, one from Dr. Gardner Robb, visiting physician in charge of the Purdysburn Fever Hospital, full of valuable information, but unfortunately not including his views or recommendations as to how to lessen the prevalence of diphtheria and scarlet fever; both diseases are a real danger, a horrid cause of anxiety to everyone, and of serious economic loss to the community. The report from Dr. N. C. Graham, city bacteriologist, from the City Bacteriological Laboratory, shows that 4,351 specimens were received for examination, and there is a report also from Professor Symmers, of the Queen's University Laboratory. It is presumably a slip in including "Vaccines" (161) and "Tuberculin diluted" (22) under the same heading as "examinations" of "ice cream," "cockles," "roast chicken," etc. In the report of Captain Barry, M.R.C.V.S., the city veterinarian, on meat inspection, one figure alone—"320 cows condemned"—shows the necessity of this department; the carcasses of 255 tuberculous cows were totally destroyed.

The whole report affords evidence of activity and advance; and it is a pity that the inhabitants generally do not take more interest in the health of their city; however, the educative effects of the daily newspapers in their articles on the report, combined with the gradual spread of the study of "civics," will in time ensure for the authorities more and more support. Dr. Baillie refers to the necessity of having all cases of throat trouble promptly examined and treated; no one will gainsay such a statement, but it would have more weight if there had been a table from Dr. Gardner Robb reiterating in actual figures the evil effects of delay, especially in very young children; and such proof should be sent to the public press, and to every medical man, clergyman, and babies' club in the city. These annual reports, or part of them, being a stocktaking of the health of a community, should be made appetizing, and so educative, for the general public.

A slip or minor flaw appears in the third column of Table 2, page 7; the decimal point changes its position several times in the column; this tends to confusion on rapid reading. The figures under the "total" column, Section VI, page 14, are wrongly placed. A graver omission is the want of fuller reference to cancer, which caused 347 deaths, to bronchitis and pneumonia, 1,153 deaths, and to heart disease, 675 deaths. Are there no preventive measures, no warnings to the public, as regards these diseases?

### TUBERCULOSIS WORK IN BELFAST.

In his report on the work of the Belfast Tuberculosis Department in 1922, the chief tuberculosis officer, Dr. Andrew Trimble, expresses regret that the Government of Northern Ireland has not found it yet possible to take a census of the numbers and condition of the people. In the absence of accurate figures it is only possible to calculate rates on estimated figures. He notes, however, with pleasure that the Government recently announced its

Gaskell, and Dale and Laidlaw have been quite unable to find any evidence whatever in the cat, rabbit, or guinea-pig of a sacral supply, although certain of the sacral nerves definitely afford parasympathetic innervation to the bladder, rectum, etc. There is certainly evidence to show that motor and inhibitor influences reach the uterus even in these animals, but they both appear to travel via the hypogastric plexus.

In the human subject it is commonly recognized that the efferent sympathetic fibres of the hypogastric plexus have their direct or indirect origin from the cord at levels not lower than the second lumbar nerve. They are ultimately reinforced by fibres from two of the sacral nerves, usually the second and third, which afford the parasympathetic element. Between the second lumbar and the second sacral no fibres are supplied from the cord to the autonomic system. Are we to assume from the observations under consideration (1) that in woman, as opposed to the above mentioned animals, the uterus receives a sacral supply, (2) that the observations of Langley, etc., are incomplete, or (3) that the spinal anaesthetic, and presumably the pithing, eliminates one element only of the sympathetic supply proper which emanates from the cord above the second lumbar level? The only other possibility, as far as one can see, is to postulate an autonomic reflex over and above the purely local system, and independent of the central nervous system. I imagine that the latter would not be accepted by physiologists without very definite evidence.

It would appear most important, in view of these considerations, to note the exact level of anaesthesia attained in each case. It would also appear advisable to conform to the commonly accepted terminology, in order to avoid misunderstanding: thus the term "autonomic" is usually applied comprehensively to include the visceral nerves in general—that is, (a) the sympathetic proper, and (b) the parasympathetic (bulbo-sacral) system. Such a term as "lumbo-sacral autonomic" inevitably creates some confusion, and is difficult to interpret in view of the facts.

Such points are not of merely academic interest. The whole subject is as important as it is difficult of approach; consequently it demands the utmost precision and clarity of expression at every step. The satisfactory demonstration of a definite and tangible form of reciprocal innervation would at once suggest a wealth of therapeutic applications in the fields of obstetrics and gynaecology alike. On this account alone there is every reason deliberately to chain our imagination to the established facts.—I am, etc.,

FRANK COOK,

Guy's Hospital, S.E., Sept. 9th.

Beit Memorial Research Fellow.

#### COLOSTOMY AFTER TRANSPLANTATION OF URETERS.

SIR,—There is no condition, I think, in the catalogue of human ills which causes more distress both to mind and body than those ailments of the bladder which are characterized by incontinence of urine. It is needless to dilate upon the horrors of such a condition.

Quite recently, to relieve this condition, I implanted both ureters in the upper end of the rectum, using the transperitoneal method. The operation was not by any means difficult and in its results most gratifying. It was when the operation was finished that the idea occurred to me of making the operation of greater benefit in the future than it has been in the past by adding a complete colostomy with division of the colon to the original procedure.

The great objection to the transplantation of the ureters hitherto has been the fear of infection spreading from the bowel to the kidneys via the ureters. This danger would certainly be diminished if the whole of the lower segment of large intestine was definitely converted into a reservoir for the urine and no longer employed for the storage of normal bowel contents. Free irrigation of this reservoir for a week or two would probably rid it of a large proportion of the organisms normal to it as a rectum. Experience alone can show whether the colostomy should precede or follow the implantation.

My own idea, based upon a limited experience, is that the implantation will be easier to do if the colon is untouched, but that immediately the implantation is finished,

at the same sitting, the colon should be divided, the upper end brought out through the abdominal wall, and the lower end invaginated into the rectum. A large rubber tube fixed in the anal aperture for the first forty-eight hours will allow the urine to escape as fast as it is secreted, and so prevent leakage at the site of implantation.

Of course, my suggestion adds another risk to the operation, but the added risk is not very great, and when the incontinence is not due to a rapidly growing tumour it holds out a hope of prolonging the patient's life and diminishing his or her suffering before the oft-prayed-for end comes.—I am, etc.,

Dublin, Sept. 10th.

THOMAS MYLES.

#### DIATHERMY IN PULMONARY TUBERCULOSIS.

SIR,—I have been interested in reading, in your issue of August 25th, the reports of the papers by Drs. E. P. Cumberbatch and F. Howard Humphris on medical diathermy, more particularly in the references to the treatment of pulmonary tuberculosis by this method. I have been using diathermy in the treatment of pulmonary tuberculosis for some two years, with very encouraging results. A paper of mine was published in the *Practitioner* in October last.

When I first began to use diathermy for this disease I was unaware that it had been previously tried. But I have since heard of other workers in both the United States and Germany who speak highly as to the results obtained. In a recent communication Dr. Burton B. Grover, of Colorado Springs, U.S.A. (the Mecca of the American tuberculous), informs me that he has found diathermy give far better results than any other method of treatment in this disease. Even advanced cases receive benefit, whilst early and moderately advanced cases show a good proportion of "arrests." My own results confirm this. I have treated advanced cases with cavitation, but have not seen haemoptysis result.

It might interest Dr. Humphris to know—having regard to the last paragraph of his reported paper—that the Ministry of Health sent their representative to inquire into my technique and results by this method in January last, and that as a result the Hull Corporation (of which I am a member) have recently installed the apparatus in their tuberculosis sanatorium at Cottingham, E. Yorks.

I might add that for the last few months I have been treating my cases of this disease with ultra-violet radiation in addition—exposing gradually increasing areas of the trunk to the tungsten arc lamp for a few minutes twice or thrice weekly. By these means, I believe, I have still further improved my results.

I do most strongly urge that this method should be brought more prominently before the notice of the profession, and be given a reasonable trial throughout the country.—I am, etc.,

Hull, Aug. 27th.

PERCY HALL.

#### SPIRITUAL HEALING.

SIR,—There seems good reason to doubt whether the medical profession generally has appreciated the extent of the movement towards the establishment of spiritual healing as a definite part of the work of the clergy. The position of the Roman Catholic Church seems to be quite clear. It teaches—I believe has always taught—that miracles may still occur, but that they must be preceded by an act of faith on the part of the sufferer. The ceremonies at Lourdes, and others derived from the practice at Lourdes, appear to indicate that the Church holds that the sufferer's faith may be sustained and comforted by the expression of a similar faith by others around him. This doctrine seems to be frankly accepted by a certain section of the Anglican Church at least; but a similar belief, not quite so frankly stated or so loudly proclaimed, appears to be entertained by other sections not generally credited with holding extreme views.

I took the opportunity recently of attending a special service, held weekly, in one of the principal churches of a large seaside town. It was very quietly conducted. After the Lord's Prayer the minister read a short address in which the efficacy of prayer was insisted upon. A long list of persons desiring the prayers of the congregation was read

British Medical Association.

PROCEEDINGS OF SECTIONS AT THE ANNUAL MEETING, 1923.

SECTION OF TUBERCULOSIS.

Sir HENRY J. GAVAN, M.D., M.C.H., President.

DISCUSSION ON

THE ARTIFICIAL LIGHT TREATMENT OF TUBUS AND OTHER FORMS OF TUBERCULOSIS.

OPENING PAPER

DR. AXEL REYN,

Medical Superintendent, Finzen's Medicinske Lysanstalt, Copenhagen.

(With Special Plate.)

I should like first to tender my thanks to you for having invited me to speak on the treatment of tuberculous disease with artificial light. I deeply appreciate the honour, and I shall, in the time allotted me, try to sketch the more important principles of this treatment and show its great value.

You know, as well as I do, that the creator of the light treatment was the late Professor Finzen. Time does not allow me to mention all Finzen's different investigations on which he based the light treatment, and, indeed, greatly helped the rapid development of all radiotherapy. I must restrict myself to mentioning only the light treatment and its results in different forms of surgical tuberculosis and tuberculous of the skin.

After a lengthy series of investigations Finzen proposed to utilize light concentrated through lenses for local treatment, and non-concentrated for exposing the whole body to light baths. These two forms of treatment are entirely different, not merely in their principles but also in their mode of action. In the local treatment with concentrated chemical light one is treating a very small portion of the part that is affected, with an extremely powerful chemical light. The treatment is based on the light's qualities of being able to destroy the bacteria and of producing inflammation in the skin, which qualities we utilize to bring about the direct destruction of all affected parts of the tissue. The light bath, on the contrary, is a universal irradiation; thus, in irradiating the whole body by chemical rays we endeavour to play upon the whole organism and to cure different diseases. No stress is laid on irradiating the affected parts, but great weight is laid on giving the surface of the human body as much light as possible.

Local Treatment.

At the beginning of his experiments Finzen used the sun as a source of light; but it was clear to him that if light treatment was to be of any great value at all in northern countries, where there is a lack of sunshine, it would be necessary to make use of artificial light. Finzen chose as an artificial light source the carbon arc light, as being, among the whole class of artificial light, that which in its properties and composition comes nearest to the light of the sun, having almost a continuous spectrum.

In further experiments Finzen showed that the ultra-violet rays have the strongest effect, and consequently he gradually employed only artificial light, for the carbon arc light contains far more ultra-violet rays than the sun, the ultra-violet rays of which are absorbed by the atmosphere. The installation used for local treatment with concentrated chemical light is composed of a 50-ampere carbon arc light lamp; hanging around the lamp there are four apparatus with four convergent lenses for concentrating the light; these lenses are made of rock-crystal, which, unlike ordinary glass, does not absorb the ultra-violet rays. Along with the chemical rays the heating rays

also are, of course, concentrated. For absorption of these a layer of distilled water is placed between some of the lenses.

Chemical rays have the power of penetrating the body, but as soon as the rays get at the tissues filled with blood, all chemical light will be absorbed by the blood; consequently if you want the light to have any effect in the deeper parts of the body the skin must be made bloodless. Finzen therefore constructed a compressing apparatus, by means of which he pressed away the blood from the spot to be irradiated. The lenses in the compressor are made of rock-crystal.

By this installation four patients can undergo treatment at one and the same time; furthermore, we have constructed an apparatus for treating a single patient (the Finzen-Reyn apparatus). The principles are quite the same as by the larger installation.

Light Baths.

I have already told you that Finzen proposed utilizing the sun or artificial light to irradiate the whole body. He was of opinion that the general effect of light on the organism could be utilized in curing a series of diseases, amongst others tuberculosis. He died, unfortunately, before he could finish his work on light-bath treatment, and it was left to others to carry out the experiments first laid down by him. In Switzerland, Bernhardt, and somewhat later, Rollier, and in England Sir Henry Gairdner, were the first to use the sun bath for surgical tuberculosis.

Having seen the excellent results that Rollier obtained, I decided to try light baths in treating lupus vulgaris and various forms of surgical tuberculosis. But we are at a natural disadvantage in regard to sun baths in the northern countries, because the chemical power of the sunlight is only very small, owing to atmospheric absorption; furthermore, bright sunny days are very few and far between. Heliotherapy, therefore, can only be used in the summer months and at the seaside, where the value of the sun is enhanced by the reflection of light from the mirror surface of the sea. In winter there is next to no chemical power in the sunlight and the weather is too bleak to allow patients to be out of doors in a naked state, and to use sun baths in closed rooms behind window panes is of no value, on account of the glass absorbing the chemical rays which escape atmospheric absorption. If the light bath treatment is to be of any benefit at all in northern countries artificial light must take the place of sunlight.

The results we have obtained at the Finzen Institute in Copenhagen have shown that this is feasible. In the beginning we only used carbon arc light simply because this light has a spectrum almost like the spectrum of sunshine. The carbon arc light lamps that we are using, both in local light treatment and in light baths, are burning with direct current, for the light we utilize is coming from the carbon on the positive carbon, and if one would use alternating current no crater would be formed.

The most favourable voltage is 50 to 52 volts in the lamp; by this voltage most chemical light is obtained, as was proved by Finzen. The voltage necessary in the construction of the lamp has to be 70 volts, for the lamp will only burn quietly and steadily if there is a small surplus in the current; this surplus has to be absorbed by a resistance. The carbons are perpendicular and the focus has to be fixed; the dimensions of the carbons are also of great importance and a point not to be overlooked.

For a 75-ampere lamp the upper carbon must be 31 mm. and the lower 22 mm. in diameter; for a 50-ampere lamp 24 mm. and 17 mm.; and for a 20-ampere lamp 12 mm. and 8 mm. in diameter. Special lamps should therefore be constructed for both local treatment with concentrated light and for the light baths, and ordinary kinds of carbon arc-light lamps should not be used, for good results will not then be obtained. In the Finzen Institute we have constructed such lamps. The lamp must never, as I have seen in some places, be enclosed in an envelope of any kind of glass, for this will simply absorb chemical light.

If we want to treat more patients at one time we use two 75-ampere lamps hanging side by side; the space

classification of various tests; the police surgeon who carries them out methodically takes, on the average, about three-quarters of an hour for each case. He has to make notes on the appearance, behaviour, and gait of the alleged drunkard, and conduct him through a series of tests of the memory and capacity to describe incidents and pictures. Simple sums in arithmetic must be done and many other things requiring a certain degree of mental and physical co-ordination. The Danish Medico-Legal Society has expressed the opinion that, provided this scheme be conscientiously followed, any medical practitioner is capable of giving a satisfactory opinion as to a motor driver's sobriety. In practice, however, the police of Copenhagen have thought it advisable to employ a medical officer, who is available for this work at every hour of the day and night, and who is therefore in a position instantly to investigate a case of alleged drunkenness. This new system seems to have worked satisfactorily on the whole, and it has been found advisable to distinguish between "drunkenness" and "being under the influence of drink." The fate of the licences of the drivers in the latter class is presumably decided according to the circumstances of each case, but the licence of a driver convicted of "drunkenness" is cancelled permanently.

#### MEDICAL MISSIONS.

SIR,—The sympathetic tone of the paragraph headed "Medical Missionaries" in the Educational Number of the JOURNAL encourages the hope that you may find space for this letter, which is written to expose two common fallacies which one often hears uttered about medical missions.

The first is that some young graduates are "too good for the mission field." (The last time I heard this was on the journey from Dieppe to London last week.) A moment's reflection will show that it is not the more competent but the less competent who should be kept at home, for, here in England, they can, in any emergency, rely on the help of a neighbouring colleague, and in the more obscure cases specialists can be called in. On the other hand, in China the medical man may be absolutely alone to treat patients who have made journeys of hundreds of miles to secure his advice and submit to his treatment. The daily activities of a doctor thus situated may embrace anything from operative obstetric work, and operations for the relief of cataract or intestinal obstruction, to the prophylaxis of plague or other epidemics and the diagnosis and treatment of obscure medical complaints—a variety of work that surely calls for the ablest and best equipped man that can be obtained. I have never met a medical missionary who thought himself "too good" for his job; on the contrary, most of us have often and often longed for the presence of one or other of our old teachers.

The second fallacy is that "only the jobs in the big teaching hospitals (for example, Peking and Chinanfu) are worth a medical man's while." While not wishing to belittle the value of an appointment to such an institution, I do protest most emphatically against the idea that these have any monopoly either of (a) interest or (b) opportunities for specialism.

(a) A friend of mine—a medical missionary in sole charge of a busy hospital—was recently offered a chair in one of these large teaching hospitals, an offer which included not merely a larger salary, but also, what was far more attractive, two years' leave at full salary before taking up the appointment, so that he might visit leading hospitals in Europe and America and familiarize himself with the recent and most advanced work on the subject he was to teach. He declined the offer, finding in his "one man" hospital in a small Chinese city (far away from a treaty port with all that holds of civilization and congenial society) need and scope for all he could give, both of ability and of experience.

(b) Specialism, while rendered possible by the extraordinary teachableness and ability of the Chinese hospital staff, must depend not less on the doctor himself, on his power of organization and especially of devotion. I believe that medical missionaries specializing in surgery

have held world records for the number of successful operations done for chronic intussusception, vesical calculus, and deformed pelvis (that is, Caesarean section for malacosteon disease). The pages of the *Chinese Medical Journal* (and doubtless of the corresponding journals for other countries) will show that even in the smaller mission hospitals physicians have been able to develop research work on specialist lines both for research and for treatment.—I am, etc.,

London, N.W., Sept. 10th.

#### AN UNFORTUNATE BROTHER.

SIR,—Dr. F. A. Storr, of Knowle Cottage, Mirfield, has recently had a serious recurrence of illness. As a result of thrombosis of the right femoral artery gangrene of the leg occurred, and this has necessitated amputation in the upper third of the thigh. A long illness in 1921-22 involved him in crushing expenditure for nursing and the provision of a locumtenent in the endeavour to keep his practice together. This recurrence of illness has strained his already depleted financial resources to the limit, and in addition his physical capacity for professional work in the future has been very seriously reduced by the loss of his leg.

The West Riding Medical Charitable Society has made him a generous grant, but we feel that if possible some thing more should be done to help him over the period which will necessarily intervene until he is able to resume some professional work. Any assistance to the fund which we are endeavouring to raise would be gratefully accepted.

Subscriptions may be sent to the London Joint City and Midland Bank, Limited (Mirfield Branch), or direct to any of the undersigned Mirfield practitioners.—We are, etc.,

T. W. SPROULLE.  
LESLIE J. MILNE.  
H. W. ELWELL.  
H. J. DAWSON.

Mirfield, Yorkshire, Sept. 8th.

#### Obituary.

##### GUSTAVUS HARTRIDGE, F.R.C.S.,

Consulting Surgeon, Royal Westminster Ophthalmic Hospital. We regret to record the death on September 8th, in his 74th year, of Mr. Gustavus Hartridge, F.R.C.S., at his house in Wimpole Street. He was a son of Mr. James Hartridge, of Yalding, Kent, and was educated at King's College, London; he took the diploma of M.R.C.S. in 1872, that of L.R.C.P. Lond. in 1873, and became F.R.C.S. Eng. in 1874. After serving as clinical assistant at Moorfields and acting as Hunterian Prosector at the Royal College of Surgeons of England, he was for a time assistant surgeon to the Central London Ophthalmic Hospital; he was then appointed surgeon to the Royal Westminster Ophthalmic Hospital; he was also lecturer on ophthalmology in the Westminster Hospital, and consulting ophthalmic surgeon to St. Bartholomew's Hospital, Rochester. He gave particular attention to refraction and was the author of a manual on the subject, which reached its sixteenth edition; he also wrote a *Manual on the Ophthalmoscope* and a book on *Retinoscopy*, and was joint author with Mr. C. N. Macnamara of a *Manual of Diseases of the Eye*. Mr. Hartridge was secretary of the Section of Ophthalmology at the Annual Meeting of the British Medical Association in 1889 and vice-president at the Annual Meeting in Newcastle in 1893.

Mr. Hartridge was possessed of kindly qualities of sympathy and gentleness which endeared him to those with whom he was familiar. There was a certain vein of shyness in his character which perhaps accounted for the rarity of his participation in the more social sides of professional work. But once this shyness was forgotten the kindness of his manner made him greatly beloved. As a clinician he possessed a sureness of observation and judgement which was enviable.

Table showing Results in Closed Uncomplicated Cases, and Cases Complicated with Sinuses or Abscesses.

| Cases complicated with fistula or abscess. |    |    |    |    |    |    |    |    |    |    |    | Closed uncomplicated cases.              |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

|

I shall refer later on to the conclusions to be derived from this fact, but here I would like to request your attention to the conclusions that Dr. Ernst comes to in his last report:

"If, in conclusion, I attempt to state which cases of surgical tuberculosis adapt best to light-bath treatment, this will be most easily done by recapitulating the cases which have proved refractory. These are the uncomplicated tenosynovitis cases, and the very old fistulous bone abscesses in the spinal column, pelves, and hip, while the later cases (of about twelve months' standing) are not particularly unfavorable to treatment. "As regards the knee, I have become more conservative in my treatment of adults with whom a fixed condition of flexion has already set in or where there are very severe capsular changes. In many of these cases it will end in resection. "Slight tuberculosis of the lungs is no contraindication for light-bath treatment, but one must, of course, consider the general state of health, especially the condition of the lungs, heart, and kidneys." The time spent in curing a patient naturally differs according to the nature and locality of the affection. Broadly speaking, one can say that children get cured more rapidly than adults, and affections of the small joints are more quickly and easily healed than those in the large joints. Very excellent results and quick recovery is obtained in tuberculosis of the soft tissues and bones. The shortest time we have needed for a cure was one

month, but often the cure has taken six months, and in some cases even two years and more; but to a doctor accustomed to treating tuberculosis this is quite natural. As a separate group I wish to mention tuberculous glands. In the first years, owing to lack of space, I treated only a very few cases, but later on the number of patients treated by radiotherapy increased more and more. You are well aware that x rays are applied to a considerable extent in the treatment of tuberculous glands; medical authorities and that hyperplastic forms give the best results, while the glands with sinuses give less favorable results. For some time I had treated the glands entirely with x rays, and only in very serious cases, with formation of sinuses, have I employed light baths; however, as soon as the accommodation permitted it, I united light in addition to x rays, for I found out that the results obtained by x rays alone were less satisfactory. The results I have obtained by the combination of carbon arc light baths and x rays and by light baths alone have been excellent, not only in cases of hyperplastic glands, but also in sinus cases; about 85 per cent. of 500 cases have been cured, among which were many severe cases of several years' duration. The results illustrate to an eminent degree the great value of carbon arc light baths in the fight against tuberculous.

THE next congress of French-speaking pediatricists will be held at Brussels under the presidency of Professor V. Pechère from October 4th to 7th, when the following subjects will be discussed: Prolonged pneumonia in children, introduced by Dr. Charles Gardère of Lyons; diagnosis and treatment of intussusception, introduced by Dr. Raphaël Massart of Paris; medico-pedagogic treatment of abnormal children, introduced by Dr. Decroly of Brussels. Further information can be obtained from the general secretary, Dr. Albert Delcourt, 78, Rue de Trèves, Brussels.

THE twentieth congress of the Italian Society of Laryngology, Otology, and Rhinology will be held at Bologna from October 8th to 10th, when a discussion will be held on otitic pyaemia, introduced by Professors Federici and Torrini. Further information can be obtained from the secretary of the executive committee, Dr. A. Fabbri, Via Santa 2, Bologna.

A SPECIAL two weeks' course in cardiology will be held at the National Hospital for Diseases of the Heart, Westminster Street, W.1, from October 15th to 27th. The fee for the course is £7.

THE National Association of Railway Travellers (79, Queen Street, Mansion House, E.C.4) has issued a circular asking for financial support with which to contest the case of season-ticket holders and other travellers by rail before the Railway Rates Tribunal.

THE Eyesight Conservation Council of America has announced that it is about to undertake a national survey of eye conditions; a previous investigation by this organization showed that in the United States 25,000,000 persons employed for gain had eye defects.

A COMMITTEE has been formed to erect a statue in memory of Charles Gabriel Pravaz, the orthopaedist and inventor of the syringe which bears his name, at his birthplace, Pont de Beauvoisin, Isère. His work as an orthopaedist was recently reviewed in this JOURNAL (August 18th, p. 288).

PROFESSOR MAX WOLFF, formerly director of the Berlin University Clinic for Diseases of the Lungs, has recently died.

THE festival of the medical saints Cosmas and Damian was recently celebrated at Luzarches, a commune in Seine-et-Oise, where relics of these saints are preserved.

THE next international congress of thalassotherapy will be held at Arcachon in 1925, when the marine treatment of rickets will be discussed.

## Letters, Notes, and Answers.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

As, owing to printing difficulties, the JOURNAL must be sent to press earlier than hitherto, it is essential that communications intended for the current issue should be received by the first post on Tuesday, and lengthy documents on Monday.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

IN order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL.

THE postal address of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is 429, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Aitiology Westrand, London*; telephone, 2630, Gerrard.
2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westrand, London*; telephone, 2630, Gerrard.
3. MEDICAL SECRETARY, *Mediscera Westrand, London*; telephone, 2630, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone, 4737, Dublin), and of the Scottish Office, 6, Rutland Square, Edinburgh (telegrams: *Associate, Edinburgh*; telephone, 4361 Central).

### QUERIES AND ANSWERS.

"R. C." asks for information regarding Moutier's solar syndrome.

"S. M. P." asks where in London he could gain experience in the "twilight sleep" method of treatment.

#### INCOME TAX.

"F. E." supplied the inspector of taxes last year through a firm of chartered accountants with certified accounts of his practice. This year he has filled in his income tax return himself and

finds that the inspector is pressing the accountants to supply a copy of his accounts for 1923.

"\* \* When 'F. E.' made his return for 1923-24 he presumably made it on the basis of the average of the result of the certified accounts for 1921 and 1922 and the profit shown by a statement prepared by himself of his receipts and expenses for 1923. We suggest that our correspondent should send the inspector a copy of this '1923' statement, first certifying it to be a full and correct statement of his earnings to the best of his knowledge and belief, and point out that as the previously supplied accounts did not show him to be undercharged to tax, the inspector may be reasonably satisfied with his own statement of account for 1923.

"J. G." keeps a motor car for professional purposes but used it for a fortnight's motor holiday and occasional outings with friends; the inspector of taxes purposes to disallow 10 per cent. of the total motor expenses.

"\* \* Our correspondent is entitled to deduct only those expenses which he incurred for professional purposes and cannot properly include in his expenses for income tax purposes the costs incurred by his private use of the car. Whether those costs are fairly represented by 10 per cent. of the total expenditure must depend on the facts of the case.

"A. B." arrived in the United Kingdom on April 4th on twelve months' leave; will he become liable to tax if he stays here less than six months, goes abroad for a period, and then returns?

"\* \* Yes, if he spends more than six months in this country in the same financial year—ending April 5th. It has also to be remembered that any person coming to this country with the intention of establishing a residence here is liable even though he is here for a shorter period than six months. Staying temporarily in a borrowed or hired flat would not constitute establishing a residence; that would depend on whether the circumstances as a whole showed that the person concerned had severed his connexion with the foreign place and had formed plans for remaining in the United Kingdom on a permanent or semi-permanent footing.

### LETTERS, NOTES, ETC.

DR. A. D. WOOLF (13, The Avenue, Highams Park, E.4) writes: I am anxious to obtain an "etherometer" as manufactured by the late Etherometer Co. of America. I have tried the usual channels in this country but without success, and would be glad to know whether any of your readers has one which he would care to dispose of.

#### SYMPATHETIC MAGIC?

"M. O." writes: I heard recently of a patient who, being refused information by her doctor as to methods of procuring abortion, inquired "whether it was true that stuffing a pad of cotton-wool into the mother's umbilicus would kill the child by asphyxiation." It would be interesting to learn whether this superstition is common. It appears to indicate a belief in "sympathetic magic," but it is difficult to understand how anyone sufficiently acquainted with elementary physiology to realize that the umbilicus has any connexion with foetal respiration could also believe that a proceeding of this sort could affect the child in any way.

#### VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 30, 34, 35, 36, and 37 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 32 and 33.

A short summary of vacant posts notified in the advertisement columns appears in the Supplement at page 121.

### SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

|                                             | £   | s.  | d.     |
|---------------------------------------------|-----|-----|--------|
| Six lines and under                         | ... | ... | 0 9 0  |
| Each additional line                        | ... | ... | 0 1 6  |
| Whole single column (three columns to page) | ... | ... | 7 10 0 |
| Half single column                          | ... | ... | 3 15 0 |
| Half page                                   | ... | ... | 10 0 0 |
| Whole page                                  | ... | ... | 20 0 0 |

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, W.C.2, not later than the first post on Tuesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *poste restant* letters addressed either in initials or numbers.

if such a tablet is of much use, and the author concludes that the potency of various preparations sold in pill or tablet form depends to a considerable extent on the ease with which they break up, and this is a matter to which the manufacturing chemist should pay more attention.

#### 189. Mercurial Treatment in Encephalitis Lethargica.

E. BILLIGHEIMER (*Klinische Wochenschrift*, June 25th, 1923, p. 1215) points out that all drugs employed in the treatment of encephalitis lethargica have failed hitherto to check the disease, though scopolamin and atropine have been found of service in the secondary conditions associated with muscular rigidity and motor impairment. But the good effects of these two drugs are only temporary and only continue so long as the drugs are given. The author has tried the effects of mercury, usually in the form of an inunction treatment (up to 5 grams daily); in a few cases in the form of injections of mercury salicylate. The therapeutic effects, which followed very rapidly, were remarkable and in most cases surprising. Records of eight cases are given and the results mentioned in four other cases. In all of his acute and subacute cases mercury had a distinct beneficial effect, and the good results were noted very soon after the commencement of the treatment. In only two of his chronic cases were good results obtained. In the most severe chronic cases either the mercury had no action or the patients were oversensitive to the drug and tolerated it badly. In the acute and subacute cases the symptoms very rapidly subsided after the use of the mercury. The author strongly recommends the treatment in all acute and subacute cases.

#### 190. The Stigmata of Late Hereditary Syphilis.

B. BARKER BEESON (*Paris méd.*, June 30th, 1923, p. 565) states that one of the most complete reports on this subject was made by Sir Herbert Smalley on 941 prisoners at Borsdal, aged from 16 to 21, of whom 153, or 16.2 per cent., showed evidence of late hereditary syphilis. Beeson's observations were made on 100 male prisoners at the Chicago House of Correction. As complete a family and personal history as possible was obtained, and a Wassermann reaction was performed in each case. Special attention was given to the ocular and tendon reflexes; 61 per cent. of the cases were white and the rest were coloured; 22 were aged from 17 to 20, 51 from 20 to 30, and the rest from 30 to 65; 39 (26 white and 13 black) presented stigmata of late hereditary syphilis. The most characteristic stigmata, such as Hutchinson's teeth, Argyll Robertson pupil, Romberg's sign, and loss of knee-jerks, were rarely found, whereas less pathognomonic stigmata, such as the highly arched palate, and minor dental anomalies, such as vicious "implantation" and marked separation of the teeth, were relatively frequent. The Wassermann reaction was positive in 29 cases. It may be of value in detecting obscure cases, but it may be negative in spite of the presence of important stigmata of late hereditary syphilis. A family history of numerous deaths during infancy was obtained in 9 cases.

#### 191. Treatment of Psoriasis.

K. HERXHEIMER (*Klinische Wochenschrift*, July 6th, 1923, p. 1369) records his experience of the treatment of psoriasis. As regards internal treatment, he is of opinion that, if possible, intermittent courses of arsenic should be tried. But often this treatment fails; and, if long continued, long pauses should be allowed between the separate courses. Sachs in Vienna has recently recommended intravenous injections of 10 to 20 c.cm. of a 20 per cent. solution of sodium salicylate. From his own experience, the author thinks this treatment is of service, but its effect is only symptomatic. The results obtained by Brock's method of treatment of psoriasis (the action of x rays on the thymus gland) have varied much. For external treatment many authors regard chrysarobin as the best application, but the author prefers certain coal-tar preparations. In the last thirty years he has tried the action of various new coal-tar preparations in 500 cases of psoriasis, and found that three of these deserve to be specially recommended—lithantrol, carboterpin, and carboneol. The first two can be employed in ointments of 10, 20, 30, or 50 per cent. strength; also in 5 to 50 per cent. spirit solutions. The time required for successful treatment does not exceed that for chrysarobin. The linen is little stained by lithantrol, somewhat more by carboterpin, but the stains are removed without much trouble. Tar acne is very seldom and tar eczema and nephritis almost never observed. For long persisting patches, carboneol is recommended, but it stains the linen. The author recommends that carboneol should be used as a paint, though it may be also employed as an ointment or paste. The old *pix liquida* preparations have also a very good action; and, on account of its cheapness, oleum fagi (oil of birch tar) is to be recommended, but the staining and smell are objections to its general use.

## Surgery.

#### 192. Diagnosis of Carcinoma of the Tail of the Pancreas.

Two cases of carcinoma of the tail of the pancreas are reported by T. SCHOLZ and F. PREIFFER (*Journ. Amer. Med. Assoc.*, July 28th, 1923, p. 275). The x-ray findings in both instances were so characteristic of gastric malignancy that a definite diagnosis of carcinoma of the stomach appeared justified. The clinical findings, on the other hand, were not very typical of any organic lesion of the stomach; in fact, there were, in the clinical picture of these two cases, several points which spoke against such a diagnosis. In both cases surgical intervention disclosed a tumour of the pancreas. An interesting clinical point is mentioned with regard to one of the cases. Schmidt has stated that bronzing of the skin in pancreatic lesions is always accompanied by sugar in the urine (bronze diabetes), this being due to an interstitial inflammation of both the pancreas and the liver. An exception to this rule was the case in which there was a most characteristic bronzing of the skin without sugar in the urine at any time. A plea is made for a closer co-operation between clinician and radiologist, and an interpretation of x-ray findings along clinical lines.

#### 193. Plating in the Treatment of Fractures.

A. STILLMAN (*Annals of Surgery*, July, 1923, p. 75), reviewing the advantages and disadvantages of metal plates in the treatment of fractures of the long bones, finds that statistics confirm the general opinion that union is delayed by plating, though the time elapsing after fracture before operation is performed may be as much a cause of delayed union as the plating. Since the original fracturing injury affords the greatest stimulus to repair, operation, by disturbing such repair after it has begun, renders it necessary for repair to start afresh with the original stimulus somewhat spent. It is difficult to decide when union has actually taken place after plating, since the plates give firmness to the fracture, but it may be estimated by the amount of callus as shown by x rays. The time of union after plating is of secondary importance to the production of an anatomically and functionally correct limb, which is of more frequent occurrence after platings than after treatment by the closed method. The three main indications for the use of plates are: (1) when reduction cannot be properly maintained without direct fixation; (2) when non-union results from too great separation of the fragments; and (3) when faulty union has taken place. From an experience of 66 platings (once of the clavicle, 4 times of the humerus, 5 times of the ulna, 9 times of the radius, 15 times of the tibia, and 32 times of the femur) the procedure is justifiable in competent hands, but now that fractures of the femur are usually treated by suspension and traction plating is not so frequent, but when limited to the smaller bones should become more useful.

#### 194. Diverticula of the Large Intestine.

R. BENSAUDE, A. CAIN, and P. HILLEMANT (*Ann. de Méd.*, May and June, 1923, pp. 432 and 547) show that diverticula of the large intestine consist of herniae of the mucosa through the muscular coat. Sometimes these are obvious to the naked eye, in other cases they are only seen on microscopic examination. Three points in their etiology are well established: they are more commonly seen in males, they are only found at an advanced age, and they attack obese subjects. They are rarely seen before the age of 40. Diverticula may be only discovered at autopsy or during the course of an operation, or they may become inflamed and give rise to a condition of "diverticulitis," while sometimes a diverticulum perforates into the peritoneal cavity. Diverticula are most commonly found in the sigmoid, at the point where the vessels from the mesosigmoid perforate the walls of the intestine. They may be present in considerable numbers; exceptionally they are single. Frequently there is a considerable deposit of fat around them. The condition known as "peri-diverticulitis" is due to chronic inflammation developing round a diverticulum which may be lost in the centre of the tumour. They may be congenital in origin or may arise from the glandular element of the gut, perhaps due to obstruction of their lumen in cases of chronic constipation. Others consider they are due to mechanical causes similar to the diverticula found in the oesophagus. The authors consider that diverticula may be produced occasionally by traction of a tumour or adhesions; more often they are due to increased pressure within the bowel associated with weakening of the walls. The sigmoid appears to be the site of election for their appearance, as it is affected with violent peristaltic movements during defaecation, especially in constipated individuals. If the walls of the gut are weak the conditions are favourable to the development of diverticula. Further, the faecal material in this situation is

RECEIVED

In conclusion, I should like to say some few words about local treatment. This, as has already been stated, is used in the treatment of lupus vulgaris and other kinds of skin tuberculosis; but many sinus cases in patients suffering from surgical tuberculosis are also undergoing local light treatment with excellent results. Especially in cases of tuberculous glands with sinus formation is local light treatment of great importance, for it hinders the development of lupus vulgaris in the scars and brings about a more rapid and certain cure of the sinus.

The Finson light installation for local treatment with concentrated chemical light is somewhat expensive and complicated; other apparatus have, therefore, been constructed to take the place of the Finson one. In Germany, for example, Kromayer's mercury lamp has been much in general use; but in treating lupus vulgaris and other kinds of skin tuberculosis locally all these other kinds of lamps are much inferior to Finson's.

In the investigations made by Hansen it is shown in a very exact and careful manner that the effect of Finson's light treatment in lupus is to destroy the pathological cells. To bring about this destruction a rather penetrating light is necessary, but the concentrated carbon arc light is the only one that has the power of penetrating right into the depths of the tissue, as Finson, Hansen, Hasselback and Marx, after their numerous experiments, have pointed out. If we desire to utilize this relatively deep effect, the tissue in question must be made bloodless, as Finson has shown us by experiments on rabbits, and also in trying to irradiate lupus vulgaris without employing a glass apparatus. In this last mentioned mode of treatment lupus vulgaris Finson speaks, never brought about. If we go on and repeat his histological experiments on lupus vulgaris, after repeated irradiations, we can well understand that compression is absolutely imperative if a real cure is to be brought about.

At the Finson Institute we observe every day proofs of the correctness of this opinion, for quite a number of our patients are suffering from lupus vulgaris to such an extensive degree that for a long time we have to restrict ourselves to local treatment in the face alone, the other spots on the body merely undergoing strong radiation by the carbon arc light during the process of light baths. These spots show great improvement in accordance with the general effect brought about by the light baths, but a real cure is exceptionally rare, and, later on, these spots have to undergo local treatment, while the face, which has been treated with concentrated chemical light simultaneously with light baths, is already cured.

I emphasize this because in France Dr. Benoit has recently stated in print that he treats lupus vulgaris with local irradiation of ultra-red rays together with ultra-violet rays, without making the tissue bloodless by pressure. Dr. Benoit takes it for granted that in this manner the influences of the blood, which should again influence the local disease, Benoit, in my opinion, is quite wrong in his views, and compounds the effect of local light treatment with the effect of general treatment. With this method of irradiation he will obtain improvement, but never—or at any rate very seldom—bringing about a complete cure of lupus vulgaris, because he only gets quite a superficial effect of the local process, as we have seen in treating lupus vulgaris with light baths without any local light treatment. By this treatment we irradiate the spots with a powerful

1. The non-operative treatment is the principal one in cases of surgical tuberculosis, not only in children but also in adults.

2. Light baths (sun or artificial) are indispensable in the non-operative treatment of surgical tuberculosis.

3. The carbon arc light can fully replace sunlight, and is much superior to the mercury arc light.

4. Sanatoriums in mountain heights, as well as at the seaside, should have artificial light baths at their disposal.

5. In the treatment of lupus vulgaris concentrated chemical light is absolutely indispensable, and it is of the greatest value to combine local treatment with light baths.

**TREATMENT OF CUTANEOUS TUBERCULOSIS.**

J. H. SEQUEIRA, M.D., F.R.C.P., F.R.C.S.,  
Physician to the Skin and Phototherapy Department, and  
Lecturer on Dermatology, London Hospital.

(With Special Plate.)

I esteem it a great honour to follow Professor Reyn in this discussion. Nearly twenty-four years ago I had the privilege of attending the practice of the Light Institute at Copenhagen, under Professor Finsen, and Dr. Reyn was then Director of the Clinic. Since then I have followed with the greatest interest the developments of phototherapy, and as opportunity offered these developments have been introduced into my own clinic at the London Hospital.

My contribution to this discussion must necessarily be brief, but I would like to direct special attention to some points which are in my experience frequently forgotten.

To get the best results in the treatment of tuberculosis of the skin, and, particularly its most common variety, lupus vulgaris, one cannot rely on local measures only. I venture to urge, and Professor Reyn's communication supports my contention, that it is necessary to make our attack on the disease a combined one. We must use local measures, and on their importance I hope to say a few words shortly, but we must also use general measures.

*Local Treatment.*

In lupus vulgaris we have to deal with two very distinct types of case—(1) the type which we, in practice, recognize as dry lupus, and (2) ulcerative lupus distinguished by the earlier writers as lupus exedens and lupus non-exedens. It is essentially the dry type, the type in which sharply circumscribed spots or nodules imbedded in the skin, which reaches most satisfactorily to the local application of concentrated light, usually described as the Finsen treatment. I need not enter into the details of this treatment, but it is established that if the lesions are comparatively limited in area and in a situation where the character of the cicatrix is of importance we can get better cosmetic results by the Finsen treatment than by any other form of therapy. Where the character of scar is of less importance we can use caustics such as strong creosote and salicylic plasters, the acid nitrate of mercury, and in some regions we can excise a patch with or without grafting.

All these measures give highly satisfactory results in a number of cases of dry lupus, provided the area is not too extensive. In extensive cases the time required is the chief drawback. With the more careful inspection of our school children and the co-operation of tuberculosis officers the disease will be recognized earlier and extensive lupus will be very rare in the future.

I should like to give one word of warning as to the treatment of dry lupus. One should never try to cure it by x rays. I agree that you can destroy a patch of dry lupus by repeated x-ray exposures, but you run a grave risk of causing cancer. We, unfortunately, learnt the lesson early and for years we have endeavoured to bring to the notice of officers of hospitals and tuberculosis dispensaries

is associated with late puberty, tendency to obesity, dull intellect, the necessity for a large amount of sleep, no resistance to fatigue either mental or physical, etc.; hyperovarianism is suggested in a small, active, well developed girl, quick of eye and untiring. Hypothyroidism may be recognized by puffiness of face, dryness of skin, etc., and deficiency of pituitary and suprarenal by arterial hypotension and asthenia. For these cases 10 to 20 cc. of ovarian extract is given with either thyroid or adrenaline for ten to twelve days. (Thyroid should not be given if rheumatism is present, as it is apt, says the author, to aggravate this.) If this treatment fails, dilatation and curettage should be done, the scrapings being examined, when a diagnosis of tuberculous endometritis may be made. This may cure the condition, but if the bleeding returns in two to three months then radiation should be tried, though Delbet's method of injecting zinc chloride (1 in 10) into the uterus may be tried first, as it is often successful. As regards radiation, radium holds the advantage of acting less on the ovaries, but x rays require no intrauterine manipulation. In many cases treated by x rays congestion first occurs and the bleeding is increased momentarily; it is best, therefore, to administer the first dose just after a period. Though normal periods usually return after a certain period of amenorrhoea, it has yet to be proved that radiation does not produce sterility in many cases; in the author's opinion, therefore, radiation should only be performed in such cases as a last resort to prevent the necessity of hysterectomy.

#### 201. Etiology of Puerperal Morbidity.

IN connexion with a statistical study of about 400 cases of puerperal morbidity found among about 7,000 deliveries, E. ENO (*Surg., Gynecol., and Obstet.*, June, 1923, p. 797) notes that primiparae were twice as frequently affected as multiparae; that in about one-third of the former and two-thirds of the latter the course of the reaction was very mild and no definite etiological factor could be detected which would explain the pyrexia following delivery; and that in no fewer than 36 per cent. of primiparae and 20 per cent. of multiparae bacteriological or definite clinical evidence of gonorrhoea as an etiological agent was present. A "flare-up" of gonorrhoeal infection appeared to be produced *post partum* in cases in which there had been no prolongation of labour and no undue number of vaginal examinations. After spontaneous delivery morbidity was more common in primiparae as compared with multiparae, and the figures furnished evidence pointing to an etiological influence of long labour and repeated vaginal examinations.

### Pathology.

#### 202. Intolerance of Oxygen by Anaerobic Bacteria.

J. W. MCLEOD and J. GORDON (*Journ. of Path. and Bact.*, July, 1923, pp. 332-341), in studying the problem of intolerance of oxygen by anaerobic bacteria, have shown that anaerobes cannot tolerate more than very slight concentrations of oxygen because they produce hydrogen peroxide as soon as oxygen is available, and being very sensitive to this substance they die. When cultivated in the presence of liver catalase little or no evidence was obtained that catalase favoured the growth of tetanus, but it was found that unheated liver extract containing plenty of active catalase favoured the growth of *B. welchii*. Heating the liver extract to 70° to 80° C. to destroy catalase either removed or diminished its power of favouring growth, but all attempts to get anaerobes to grow in the air on plates heavily charged with liver catalase failed. This does not involve the abandonment of the theory that the anaerobes cannot tolerate oxygen on account of the formation of peroxide, since there is a limited range of oxygen concentration in which it is possible to demonstrate the value of catalase. It is possible also that at low concentrations of hydrogen peroxide there may be a tendency for catalase to synthesize hydrogen peroxide from water and oxygen. These authors consider that the sensitiveness of anaerobes to hydrogen peroxide is not due to their inability to produce catalase. Media about to be used for the growth of anaerobes should not be exposed to light. About eight hours' exposure to diffuse light sufficiently charges an agar plate with hydrogen peroxide to prevent the growth of *B. tetani*; a slightly longer period is required to kill off a culture which has already grown. A considerably greater exposure is required to prevent the growth of *B. welchii*, which is less sensitive to hydrogen peroxide. In all probability hydrogen peroxide is produced during the growth of anaerobes. This production of peroxides by anaerobes is probably the explanation of the green discoloration of heated blood media which anaerobes produce under certain conditions.

#### 203.

#### The Bacteriology of Pemphigus.

F. EBERSON (*Arch. of Derm. and Syph.*, August, 1923) has added yet another to the already long list of organisms which have been incriminated in the pathogenesis of pemphigus. Isolation was effected from the blood of patients suffering from chronic pemphigus; in one case was recovered from a bullous lesion of the skin. Morphologically it is an extremely small, ovoid, spore-forming, pleomorphic bacillus, occurring in pairs and in chains, arranged in parallel bundles consisting of two or three individuals. It is non-motile, Gram-positive, and, when isolated, strictly anaerobic. The most satisfactory medium was found to be a meat infusion broth, containing 0.5 per cent. glucose, together with some brain tissue in a few pieces of chipped marble. Only after several days on this broth could growth be obtained on a solid medium—one of glucose ascitic agar. Serologically it was shown that the blood of patients suffering from pemphigus was able to agglutinate the organism, and experimentally it was possible to prepare serums from rabbits with similar agglutinating property. The study of the organism in strains, though imperfectly carried out, seemed to show there was a close relation between them. In experiments on animals, the organism proved to be pathogenic to guinea-pigs and rabbits, especially the former, the definite lesions simulating the clinical picture of pemphigus in human beings could be observed. The organism has provisionally been named *Bacterium pemphigi*.

#### The Etiology of Sarcoma.

ILLUSTRATED by observations on four recorded cases, the etiology of sarcoma is discussed by J. PATRICK and BURTON (*Glasgow Med. Journ.*, July, 1923, p. 8). In each case there was a history of some form of trauma or irritation, and the respective natures of which were (a) the application of a cautery, (b) the use of CO<sub>2</sub> snow, (c) scraping by means of a Volkmann's spoon, (d) a blow by a mass of coal, all operating in the presence of a certain degree of infection. These cases appeared either to determine the actual origin of the sarcoma or the transformation of an originally benign process into a malignant overgrowth of embryonic tissue. The authors note the difficulty that is frequently experienced in distinguishing the cells of an inflammatory or reparative process from those of a sarcoma, and that each observer has his own standard of what constitutes the latter. The growths were not necessarily malignant from the start, but the possibility of conclusive proof in at least one of the cases was reviewed, both by the clinical features and repeated pathological examination. It is suggested that a more careful might profitably be directed not so much to the distinction of cellular elements as to variations in individuality of power and capacity of rapid complete repair and of tissues against irritation and trauma.

#### Blood Pressure in Students.

W. C. ALVAREZ, R. WULZEN, and L. J. MAHONEY (*Int. Med.*, July 15th, 1923, p. 17) investigated the blood pressures in 14,934 students (6,000 men and 8,934 women) entering the University of California. The observations comprise two periods, 1918 and 1920-21, the findings in the two series confirming in the main those of the first series. They found that the blood pressures of women are more generally higher than those of men and are on the average 11 mm. higher than the average pressure for both men and women gradually during the first years of adult life. For pressures ranged mainly about 127 mm. at the age of 18 and about 118 mm. at 30, while for women they were about 118 mm. at 16, about 111 mm. at 24, and about 110 mm. at 40. Among younger men hypertension is very common, 45 per cent. exceeding 130 mm. and 22 per cent. exceeding 140 mm., while among women 12 per cent. exceeded 140 mm. and 2 per cent. exceeded 140 mm. Since most of the students were under war service age it is doubtful to what extent the war influenced the pressures, if at all, and although the pressures were low in 1918 and high in 1919 they returned to original figures in 1920-21. Even the influenza epidemic of 1918-19 was not explanatory, and though the low ebb in 1918 may be a possible predisposition to an epidemic further investigation is needed for confirmation. The conditions of hypertension cannot be regularly ascribed to injections or to stress of living, and it appears rather to be an inherited peculiarity, its appearance being suppressed in women with defective ovarian function, while in those developing male characteristics, as evidenced by the distribution of the blood pressure, administration of corpus luteum extract has a restraining influence on the development of hypertension, and suggested that ovarian extracts might be of use in the treatment of high blood pressure in men.

Professor S. Rezn (London) said that the address of a record of work carried out in the Institute at Copenhagen bearing the name of Pinesen, the originator, in a sensitive sense, of heliotherapy. Professor Rezn's clinical observations served to clear up some issues which were of rather long standing as regards their solution, and it appeared that just as in the domain of x rays so in the regime of the visible and ultra-violet radiation it was necessary to refer very explicitly to the particular radiation which was in question. This explicitness was non-possible for the wave-lengths of all the radiations in medical use had been measured by the physicist, and there was much to be said for referring to the rays used in terms of their wave-lengths. The difficulty up to quite recent times had been to know which portions of the spectrum had been responsible for the clinical effects observed, and now appeared to be quite possible to assign many of the relations of the tissues to and of the radiation with wave-lengths. For most medical purposes it is sufficient to consider that region of 0.01 to 0.1 of ultra-violet radiation which extended on the short wave-length side of violet light—namely,  $\lambda = 3,800 \text{ \AA.}$  down to about  $\lambda = 2,000 \text{ \AA.}$  Experiment showed that the wave-lengths ranging from 3,000 to 2,000  $\text{\AA.}$  were very easily absorbed by vegetable and animal tissues, causing in the process of absorption

<sup>1</sup> Squeeitra, J. H.: *Lancet*, 1902, i, p. 705, and 1913, i, p. 1655. = Strand-  
berg, O.: *Zeitschrift f. Laryngologie*, 1920, BL x.

Dr. J. M. Jørgensen (Tor-na-Dee Sanatorium, Aberdeen-shire) said that he wished to refer only to the use of carbon arc lamps in the treatment of certain tuberculous conditions. One of his colleagues had visited Copenhagen last year and was so impressed with the results of the treatment of painful tuberculous laryngitis by exposure of the body to the light of the carbon arc lamps that it was decided to put in an installation at Tor-na-Dee Sanatorium. This was done recently, but so far he had treated only two patients, suffering from tuberculous laryngitis. In both, the laryngeal disease was severe and there was great pain, preventing the patients from taking sufficient nourishment. In the first case relief of pain was obtained in two weeks, and although the treatment was abandoned at the end of that period owing to the occurrence of pyrexia, there had been no recurrence of the pain in the larynx for four months. The patient had advanced pulmonary disease which was progressive, and the outcome was very bad, but at all events the carbon arc lamp treatment had given her comfort and had thereby prolonged her life considerably. The other patient had a moderate pulmonary disease and was almost able to get up, but he had an exceedingly painful larynx and was sent to Tor-na-Dee for two to three months by the carbon arc lamps. He had been having large quantities of morphine together with local anaesthetics insufflations, sprays and lozenges, without which

pitfall—namely, deep-seated disease without surface evidence. Many years ago, when I first started doing artificial pneumothorax, I had no x-ray installation at my hospital on which to rely for help. In one case in particular I remember collapsing a very bad lung where the other lung appeared to be clear, with the result that oedema developed in the apparently clear side and the patient died. At the autopsy it was painfully disclosed to me that the "better lung" was full of deep excavation and abundant disease, none of which gave signs at the surface. At the time this came to me as somewhat of a shock, but experience has taught me that it was an excusable accident. Given advanced hilus tuberculosis and one-sided signs, it is practically impossible to tell from physical signs what may be happening in the depths of the other lung. On the other hand, with symptoms which may or may not be due to tuberculosis, and with absence of stethoscopic signs, it is fortunately quite possible to exclude or confirm hilus tuberculosis—that is, we can diagnose the disease, but details as to its distribution in the depths of the lung are quite another matter.

What I want to emphasize in the matters I have discussed is the pitfall which deep-seated tuberculosis presents to the unwary. Fortunately this form of the disease is often of mild aspect, and a holiday rest and some attention to health may get the patient well, undiagnosed. But this is by no means always the sequel, and if you wish to catch your case early, and to avoid the risk of hearing that your favourite "neurasthenic" has died of tuberculosis, you must keep this pitfall in mind. Never be put off by absence of stethoscopic signs; this means nothing. Take the symptoms seriously until it can be clearly demonstrated what is their cause, or at least that it is not tuberculosis. My experience is that it is deep-seated disease which especially provides advanced cases and swells the mortality table in tuberculosis, and this solely, I think, because the condition remains undiagnosed and hence untreated in its earlier stages. Undoubtedly the disease may spread slowly with but slight disturbance of health, and only after years may it be recognized, too late, that the patient's resistance is finally overcome.

#### *Deceptive Signs.*

And now I will turn to a quite opposite aspect of tuberculosis, with the object of reminding you that stethoscopic signs, on which we physicians are very apt to rely, may also deceive us at the other end of the scale—that is, that in cases of tuberculosis crepitations do not always indicate active disease. Many are my patients, or former patients, going about their ordinary avocations with an area of crepitations over the site of their most advanced lesions. For the most part such cases harbour a deep cavity, but this is not always the case. The condition is generally due, in my opinion, to a dilatation of small bronchi or bronchioles—a bronchiolactasis—brought about by the contraction of underlying or surrounding tissues. Often the sound is a dry crackle, but at other times, particularly in conditions of catarrh or after a haemoptysis, moist crepitations may be heard. Such signs are very apt to be taken for those of active disease—indeed, good observers may differ as to their significance in a given case. Particularly difficult is it to exclude activity, or to persuade others that tuberculous activity is absent, in cases of haemoptysis or of fever in such cases. Nevertheless a prolonged experience of tuberculosis has convinced me that in cases of long standing, and where disease has reached to stages of cavitation, haemoptysis, febrile attacks, and moist crepitations may all be found in the entire absence of tuberculous activity. Not a few of such cases have recurrent attacks of haemoptysis without further disturbance. The febrile attacks are due to secondary infections and are often periodic, sometimes recurring to a day every three or four weeks. If such a case, being known as tuberculosis, has retained crepitations over a large area of one lung, it may be difficult to decide and difficult to persuade others that, *qua* tuberculosis, the condition is arrested. Where, moreover, disease has been widespread, it must be admitted that it is unwise to rely too much on such arrest where secondary infections are constantly disturbing the balance.

Another sign of tuberculosis which may persist in an embarrassing way long after the disease is in abeyance is the presence of sputum containing the tubercle bacillus. Patients are known to me who have been well and at work for periods up to eight years at least with no relapse, but with tubercle bacilli still present. I suppose in such cases there exists an unhealed sinus leading to a caseous area at some spot. Truly in tuberculosis things are not always what they seem, but it was especially the possibility of crepitations without activity to which I wished to direct your attention. Do not, however, bank too much on this possibility in individual cases, or they may let you down.

#### *The Stethoscope as a Pitfall.*

Now I have taken two pitfalls in the diagnosis of tuberculosis and its activity, both directed towards warning you against too great reliance on the stethoscope as opposed to other means of diagnosis. The stethoscope is a valuable instrument, so long as there are no holes in the rubber, no wax in the meatus, and no prejudice in the mind of the user, but it is not, or should not be, the alpha and omega in the diagnosis of pulmonary tuberculosis. It may, as I have pointed out, "omit to mention," and it may even deliberately lie. I do not, on this account, recommend its abolition, for in the hands of those who fully grasp the situation its silence will not deceive, and its lying, like most lying, will not sound quite like the truth. But it should be put in its due place as one only of the sources of information as to what is happening in the organs of the chest.

#### TREATMENT.

##### *Dangers to the Early Case.*

I will now turn to the subject of treatment, and the point which above all others I wish to stress is the harm which the patient may do himself during the stage when he is awaiting a definite diagnosis, or at any rate awaiting treatment. The wise practitioner will confine his patient to his home or even his room where he suspects tuberculosis but has not yet confirmed his suspicion. This may be done on the excuse of a rest temperature chart, and if this shows fever the patient should be kept to bed or couch. I am convinced that the active stage could be vastly shortened, with the result that disease would spread less far and recovery be more complete, if cases were treated thus for acute illness, as indeed it is, at the immediate outset. What, instead, happens as a rule? The patient goes about his occupation for weeks or months after definite symptoms have commenced, and thereby greatly prejudices his chances of recovery. This is often, of course, the fault of the patient alone—he may never have visited his doctor during these early stages, or he may refuse to follow advice. But such advice must be insistent, and pressed with real conviction, and with the force of massed medical opinion behind it. All those who speak with authority are at one on this need of rest at the outset, only they do not speak loudly enough. The cry is for early diagnosis, and rightly enough; but the doctor who has started precautionary treatment before he can deliver his diagnosis has gone one better, and has earned, even if he does not get paid, the real gratitude of his patient. If a mistake has been made his conscience will be easy—he has done the right thing, and whatever was wrong with the patient other than tuberculosis the rest was probably beneficial.

When the case has been diagnosed start a resting régime right away; remember that the case came to you for "symptoms," and these mean active disease whether there is fever or not, and active tuberculosis, like any other active inflammation, needs, above all things, rest.

The lung is a difficult organ to rest, but its movement can be curtailed by bodily rest and absence of talking, and its blood supply lowered by damping down the systemic circulation with which it is in continuity.

#### *The Therapeutics of Rest and Exercise.*

Let us inquire a little into the rationale of rest, and incidentally of exercise, in the treatment of pulmonary tuberculosis.

no practical value at the present state of development. I consider it my task on this occasion to sketch the main lines upon which, according to the experiences gained by ourselves and others, we are now working at the Vejle Sanatorium.

#### General Remarks on Indications.

When a case of advanced tuberculosis does not show any improvement or any hope of lasting cure by ordinary sanatorium treatment, and when other special remedies are out of the question or have been tried in vain, then only do we venture to consider whether the case is fit for collapse treatment. This is settled in accordance with the rules which for many years have been laid down by the leading pneumothorax experts. If the decision is taken in favour of collapse, this is always tried at first in the most ideal method available—namely, by artificial pneumothorax. Whether this method can be carried out or not can only be fully ascertained by a considerable technical and clinical experience. The result of such careful attempts is the only means by which the case can be classified into one of the three groups mentioned above. In many cases a prolonged observation is necessary, and transitional cases are common. Nevertheless, the three groups of cases form a natural index for our further discussion, in which the question to be solved is: How can we provide the best possible conditions for the single cases belonging to each one of the three groups?

#### I. Cases with Complete Pneumothorax without Noteworthy Adhesions.

Cases of this group, when not complicated with active disease in the other lung or in any other organ, generally prove successful, showing a marked improvement of the general condition and disappearance of the local symptoms (cough, sputum, tubercle bacilli). Examination by the stethoscope and by x rays shows a complete lung collapse, with an endopleural pressure of zero. Provided no complication occurs, no further operation is done. In such a case the optimum pressure and the length of interval between the instillations are settled according to the clinical observations. The time when the patient is allowed to start work and continue the treatment as an out-patient is decided according to the circumstances of the case. The duration of the treatment is fixed individually; but as a rule the pneumothorax is maintained for at least three to five years in order to avoid relapse. While the treatment is being discontinued the patient is kept under close observation (preferably as an in-patient) so as to enable us to re-establish the pneumothorax, if there is any sign of recurrence, before the pleura is obliterated by the adhesions which unavoidably arise after a long pneumothorax treatment.

Should any complication occur, particularly a pleuritic effusion in the pneumothorax, special care is taken to avoid any injurious effect. By frequent fluoroscopic examinations of the patient in different positions of the body it is observed whether any secondary adhesion of the lower lobe is threatening complete collapse. If this—or any other local or general symptom—indicates an evacuation of the exudate, that operation is performed in combination with successive instillations according to the special technique worked out for this purpose. Thus attended to, effusions do not ordinarily influence the result of the treatment.

This last point leads us to a discussion which, however, is of much importance—namely, the bearing of the pneumothorax treatment upon the treatment of ordinary pleurisy with effusion. The facts revealed to us from pneumothorax experience have forced us to revise the indication as well as the technique of aspiration in such cases.

We have adopted, as the normal method for evacuation of pleural effusions, a replacement of this with an artificial pneumothorax. This method presents very beneficial conditions, not only in cases with serious effusion, but also in cases of emphysema. Even when mixed infection (for example, pyopneumothorax) was present we have been able by this means to treat purulent effusions without operations which result in a chronic fistula with continuous or periodical discharge. Besides the great technical and clinical advantages, this method is of prophylactic value in cases of advanced tuberculosis, for which a continued lung collapse might later on be demanded. The addition of instillation to the ordinary aspiration has in such cases checked the development of adhesions and thus we have been able to introduce pneumothorax treatment successfully before unavoidable adhesions had been formed.

In continuation of the cases of the former group we find but with localized, extended adhesions—Thoracotomy with Cauterization.

II. Cases with Complete or Almost Complete Pneumothorax but with Localized, Extended Adhesions—Thoracotomy with Cauterization.

In continuation of the cases of the former group we find here a certain number deriving the full benefit of artificial pneumothorax in spite of adhesions visible on the screen. In such cases we do not consider any further operation justified. On the other hand, if in spite of the establishment of the largest possible pneumothorax continued observation shows that the result is a failure, we endeavour to have the adhesions removed so as to neutralize their injurious influence. Thus far several different methods have been published for this purpose. Having been tried, we find that the only method of endopleural operation which we can recommend has a double value—namely, diagnostic and therapeutic. Although the x-ray examination in some cases affords a fairly clear diagnosis of the endopleural condition, the introduction of thoracoscopy by Jacobaeus has enabled us to obtain a direct localization, which has often corrected or at least supplemented the picture presented to us by more x-ray examination. With sufficient practice it is possible to obtain a surprisingly large field of view, and it is relatively easy to see the existing adhesions and their attachments to the lung and to the chest wall.

This diagnostic method has proved its particular value since Jacobaeus' method led by his experiments to work out a method of removing the adhesions under the guidance of a long metal rod inserted into the pneumothorax at the end of the thoracoscope. By means of a platinum wire at the end of a long metal rod inserted into the pneumothorax found it possible in certain cases to cauterize through the adhesions, and thus to secure the complete collapse of the lung.

This method has been adopted by us since 1918. Our experiences concur with those published by other authors who took advantage of Jacobaeus' happy idea. Thus far we feel justified in stating with Jacobaeus that "although it has been impossible by this method to obtain as high a percentage of clinically improved cases as in cases of simple pneumothorax without adhesions, the procedure is of permanent value in a limited number of pneumothorax cases with string-like or membranous adhesions."

In order to ascertain whether this method can be used in a particular case put before us we perform a thoracoscopy. If we then find the case to fulfil the conditions for cauterization, or, at least, to justify an attempt, the operation is done at the same sitting. In some cases we find it very easy during one short sitting to cut the adhesion; in other cases a larger adhesion or a system of adhesions is difficult to reach and so difficult to sever that we have to give up the attempt owing to technical difficulties; and finally, in some cases mere thoracoscopy immediately reveals that the operation should not be tried at all.

Apical adhesions which kept the lung tied up to the cupola were usually difficult to reach: lateral adhesions, on the other hand, could easily be dealt with when they had been extended to the highest possible degree by the pneumothorax. String-like, hour-glass shaped, or membranous adhesions of considerable thickness were severed without much difficulty, and also basal adhesions when properly extended. On the other hand, we did not consider it advisable to enter upon the cauterization of surface adhesions, as the cauterization of lung tissue may involve the risk of haemorrhage and the opening of tuberculous foci and cavities with a consequent infection of the pleura. This last complication of the operation is the most serious one which so far we have experienced. Other authors have published cases of more or less profuse haemorrhage from the burnt-off stumps; this complication should always be kept in mind, and if it occurs, should be treated according to the technical rules (cauterization of

about the indication, technical details, comments referred to Jacobaeus' recent publication—*Thoracotomy and Observation*, Lund, 1922, pp. 122, 123, 124, 125, 126, 127, 128, 129, 130, 131, and vol. II, No. 97 Acta Chirurgica Scandinavica, 1922, p. 103, and December 2nd, 1922, p. 104.

doubt that movement and intermittent flushing with blood are the wrong treatment for them. We have taken as our text disease but recently, or even incompletely, diagnosed, but it must not be supposed that all such cases are really "early," or that disease may not already be of a serious nature at the moment of its discovery. If it is deep-seated, especially, it may already be extensive.

There still remains a further reason for rest at the beginning of the illness called pulmonary tuberculosis—namely, the need of the body for its physical recuperation. "It needs a given amount of energy," remarks Joslin, "to meet the demands of ordinary metabolism; it requires an extra amount to meet the extra demands made by a disease like tuberculosis; and it requires still more to fight the infection and bring about a healing." Pottenger says, "The disease-fighting power of a patient will depend on his ability to maintain an excess of energy after meeting the natural metabolic requirements of the body,"<sup>2</sup> and for this adequate rest is required.

#### Practical Considerations.

And now what does all this "boil down to," to use a colloquial phrase? That pulmonary tuberculosis, and the suspected case also, should be treated as a serious matter unless, or until, it can be shown to be otherwise. That bed, or at least rest on a couch, is the right place for it at the outset, and pending complete diagnosis, and that this should be continued as long as, and beyond, the period of active symptoms. Especially must the patient be prevented, where possible, from "settling up his affairs," which means, in many cases, a strenuous attempt to put several weeks' business into a few fevered days. If it is put to him frankly that this may mean a serious prolongation of his illness, or worse, it often becomes apparent that this "settling up" is not so indispensable as it at first appeared, and a relative or friend can be deputed to carry it through. In cases where fever is a prominent symptom—cases, therefore, which will probably require the training of a sanatorium course—it is necessary to carry on bed treatment for a considerable period. If the conditions are suitable this early rest period can sometimes be advantageously carried on at home, if the friends can be trusted, or a reliable nurse is obtainable. Sanatoriums do not provide for many bed cases, and therefore it is convenient to get through a good part of this period before the patient is sent. There is also this to take into consideration—that in institutions for the treatment of pulmonary tuberculosis, whatever class they serve, there must always be a bias towards getting their patients up and about, and pushing onwards towards convalescence. Convenience, economic forces, and generally the patient's desires all push in this direction, and whatever the doctor's views may be they are likely to get carried in this direction also. The tendency is to curtail the initial resting period.

And now I feel you will be mentally asking what I consider this period of rest should run to. And this I find very difficult to answer in general terms—it is so very much a question for individual consideration. For cases running fever one may perhaps say *double* the febrile period, but in no such cases should the resting period be shorter than a couple of months. In cases of slight exacerbation in an old tuberculous case the resting period may often be more curtailed than in a first attack. With disease of decided amount and activity a period of four to six months' rest is none too long; and for the hospital class, in particular, owing to their ignorance of the dangers, and inability to obtain frequent medical observation, a long resting period at the outset is most vital. It is to be presumed, though I have not mentioned it, that the maximum of open air is combined with this rest in all cases. Rest may be in bed (and should be in febrile cases) beside the open window (preferably with the sashes removed), or on a balcony, or in many cases divided between bed and an outside couch (but stairs must not be allowed). A matter worth mentioning with regard to rest treatment is that the patient's "tolerance" to auto-tuberculin is apt to fall low during prolonged rest, so that but slight causes may lead to rises of temperature. This can generally be ignored, and "toler-

ance" can be readily built up again when it is decided that rest has been carried far enough.

When the bed period has been carried through, then will begin the period where constant attention, resource, and knowledge are most necessary—namely, the period of graduated movement and re-establishment of tolerance. This time, in cases of any seriousness, is most safely carried through in a sanatorium, where daily supervision is possible, and where conditions and surroundings are arranged to facilitate this end. Where rest has been carried on till disease is really quiescent, then the period of graduated convalescence can be carried through with more confidence and safety.

#### Pratt's Class Method.

At the conclusion I might add a few words on the most modern application of rest—namely, what is known as "Pratt's class method" of treatment, practised with success among the tuberculous poor of Boston, and also since in Montreal and elsewhere. The patient is put to bed in his own home under the maximum of open air allowable, and remains there for several months. He is visited at regular intervals by a visitor, generally a nurse, records are kept of his progress, and when it is considered safe for him he attends once weekly at a centre or "class," where he is seen by the doctor, weighed, and the names of those who have gained most weight, and those who have spent longest in the open air, are chalked up on a board. The patients chat among themselves and are given a short "talk" by the doctor, and then return to their beds. Each class is limited to twenty-five, and competition among them in the battle for health becomes very keen. Adams noted that in Montreal these patients gained twice as much weight as did similar cases treated in a sanatorium under more rural conditions. The average bed rest among Pratt's cases was four months, of "graduated exercise" combined with bed rest four to seven months, and the whole treatment ran up to a year and sometimes longer. When we remember that recovery from tuberculosis must take at least a year and often two or three years, according to what hold it has been allowed to get at the outset, it will be seen that this is not over long for treatment.

And now what were the results? Comparing them to those of Frimley and of Midhurst Sanatoriums in this country, they may be stated as follows:

| Years after Discharge. | Frimley (at Work). | Midhurst (Well or Alive). | Pratt (at Work). |
|------------------------|--------------------|---------------------------|------------------|
| 1                      | 61 per cent.       | 69 per cent.              | 95 per cent.     |
| 5                      | 39 "               | 39 "                      | 71 "             |
| 10                     | —                  | 35 "                      | 50 "             |

These are striking figures, and though Pratt's cases (though unselected and all positive to tubercle bacilli) amount to but 191, and hence are over small for statistical valuation, still the superiority seems too marked to be accidental. If this claim is substantiated, and I see no reason to doubt that it will be, there seems little doubt of where the secret of success lies—namely, in the institution of rest at the outset. These patients went to bed when otherwise they would have been walking about, and perhaps trying to work, and they remained in bed over the dangerous period of active disease. It is as an illustration of this point that I have introduced this system and these figures to your notice at the end of this talk, and it is on this note that I should like to finish. Let tuberculosis be treated, however mild the symptoms, as an acute illness at the outset, and I feel sure we shall notably reduce its mortality. Do not wait for the diagnosis to be established; especially do not wait for tubercle bacilli, which can never be trusted to keep an appointment; do not wait for such further investigations as the diagnosis may necessitate; do it now, as the advertisers say! Put your patient at rest and keep him there till your suspicions are confirmed or otherwise, and you can greet him hereafter with an easy conscience in the Elysian fields.

In two of these, however, the pneumothorax had to be cancelled soon after the operation, as the continuation of the operation was not possible. Nevertheless, the result remained good. In the third case post-operative exudate developed inside the pneumothorax and caused an expansion of the soft part of the chest wall, thus hindering the collapse; the patient died a few months later.

We have come more and more to the conclusion that in cases of universal affection of the lung a partial and ineffective pneumothorax should be discontinued in favor of a complete thoracoplasty. The plan of a complete operation, however, has often to be modified according to the extent and to the special localization of the disease. In the case of a particular lobe which involves the main part of the affected lobe the removal of the ribs should be done to a larger extent. If, on the contrary, the upper or lower lobe is only slightly affected, the plan of the operation indicated is a relatively slight resection corresponding to the better parts of the lung. In the same way a universal affection of the lung may need a different degree of universal collapse. In cases of large cavities and serious disease all over the lung, a more radical removal of all the ribs is indicated. For a universal, but nowhere very destructive, chiefly tubercle affection a smaller resection (after Williams' method) may be sufficient for an effective collapse.

(2) The problem of whether a complete thoracoplasty should be performed in one, two, or even three stages, has caused a good deal of discussion. We have been wavering rather and thither on account of the different experiences gained during our work with the operations. Our present standpoint is to individualize in this respect too. In making our plan of operation we consider the general condition of the patient as well as the condition of the lungs to be the deciding factors in this respect. If the patient is a tall person with strongly adherent muscles, causing difficult and violent manipulation during the operation, this should always be done in two stages. On the contrary, a lean person enjoying fair general health may very well be operated upon in one stage. A weakened and intoxicated patient with a rapid pulse is always operated on in two stages. A doubtful condition of the "good" lung is in favor of two stages, as a gradual collapse of the diseased lung is likely to be tolerated better in such cases than a sudden one.

If we feel any doubt as to the decision we consider the two-stage operation to be less risky. In some cases we leave the question open until, during the operation itself, it is seen whether the patient is certain to tolerate the completion of the operation in one stage.

Having settled the plan of operation for a particular case according to the above lines, the details of the technique form the next problem to be solved. Very careful attention to all the special details of the operation and the post-operative treatment is of great importance. For further information in this respect the reader is referred to an article by Sangman in *Tubercle* (1920, vol. 1, No. 7),\* in which a full description of our technique is given. Since that article was published no noteworthy modification has taken place in our technique, except with regard to the anaesthesia. In addition to the local anaesthesia with novocain-adrenaline, which we are now less inclined to use in as large doses as recorded in the article mentioned, at the end of the operation (when the more painful resection of the upper ribs begins) we administer a light ether anaesthesia, pushed far enough to neutralize the pain but not to abolish the cough reflex. This modification, when properly administered, does not cause any serious complication. At the same time it has made the operation less feared by the patients; it also assures the operator of more convenient conditions during the most difficult part of the operation.

A critical survey of our results with thoracoplasty shows the following figures: Death from the operation occurred in 9 cases. Of the remaining 56 patients, 64 obtained a post-five result (43 were relatively cured or much improved, 12 improved); 2 of these patients died later on of epidemic influenza; 32 patients did not derive any benefit from the

\* A later article by Gravesen is published in *Tubercle*, 1921, vol. 11, No. 9.

#### IV. Cases of Insufficient Collapse with Simple Thoracoplasty

An additional group of such cases has still to be considered. The fullest possible extension of resection of the ribs from the posterior incision (Sauerbruch's "hook incision") might fail—particularly in cases of large apical cavities we have found the collapse of the lung to be insufficient. In such cases we have added to the plan of operation a resection of the anterior ends of the upper ribs (except the first, which is usually inaccessible for removal together with the second stage of the posterior operation or as a separate third stage of the operation. Even when this precaution is taken complete collapse was, in a very few cases, not yet established; x-ray examination still showed of sputum with tubercle bacilli continued.

Influenced by such observations we have in a few cases added to thoracoplasty an extrapleural apicoectomy from the anterior incision. In two of the cases the cavity thus produced was plugged with gauze and was allowed to heal gradually by granulation and retraction. In one case the cavity was filled with fat, transplanted from the abdomen of the patient (Tubber, Bull). Of the two former cases, in one we did not succeed in causing the bacilli to disappear from the sputum (the patient died very soon afterwards of rapid development of the disease), whereas in the other case a positive result was obtained—the bacilli disappeared, but an influenza pneumonia later on handicapped the effect. In the case in which fat-transplantation was performed in addition to the thoracoplasty, the tubercle bacilli disappeared and the patient is practically cured.

In one of our cases, which is not included in the above figures because of its unique position, we accomplished a satisfactory collapse by an apicoectomy only (through an anterior resection of the second rib), together with transplantation of fat into the artificial extrapleural cavity. The disease (small cavity) was in this case so well localized to the apex that it was considered possible to avoid the extensive resection of ribs. The patient got on well, the sputum and patient was discharged only very recently. Cases like this are very rare indeed, and we do not believe that this method has any large field of indication compared with thoracoplasty. By anticipation we have so far kept plastic resections. In anticipation we have so far kept plastic resections. In anticipation we have so far kept plastic resections.

Still greater interest is connected with the following figures, showing the fate of 69 patients discharged more than two years ago, after thoracoplasty. From two to seven years after the operation the condition of health was reported as follows (all cases, including those of death resulting from the operation, are recorded):

|                                           |                     |
|-------------------------------------------|---------------------|
| Fit for work                              | 31 = 44.9 per cent. |
| Unfit for work on account of tuberculosis | 7 = 10.1            |
| Died from tuberculosis                    | 22 = 31.9           |
| Died from other causes                    | 2 = 2.9             |
| ...                                       | ...                 |
| ...                                       | ...                 |

These results, compared with those recorded in the former tables (p. 506) have led us to the conclusion that although thoracoplasty has a greater risk and a smaller result to be expected from the former operation results in a great improvement in the prognosis in such cases as are deprived of the effect of the pneumothorax treatment.

commemoration of my great teacher and friend, the late I cannot close these remarks without a few words in been employed by us. In order to supplement the effect of that operation) so far by Sauerbruch as a preparatory procedure for thoracoplasty modication of plugging the extrapleural cavity with the pleural cavity. Neither has phrenotomy (recommended by paraffin (Barr). In anticipation we have so far kept plastic resections. In anticipation we have so far kept plastic resections. In anticipation we have so far kept plastic resections.

results in definite cases of pulmonary tuberculosis. Of 82 controls, all were negative save 3. Of these 3, 2 were cases of leprosy. (We might mention in parenthesis that we have also found cases of leprosy giving a positive result with tuberculous antigen; one was a case of Addison's disease and was therefore in all probability suffering from an active tuberculous lesion.) Miller,<sup>4</sup> using an antigen made by grinding up tubercle bacilli with salt, obtained a very high percentage of positive results (96.8 per cent.) in cases with tubercle bacilli in the sputum, while of 243 Wassermann positive serums, 7 only gave fixation of complement with tuberculous antigens; of these a diagnosis of tuberculosis was subsequently established in 5 and could not be excluded in the remaining 2.

Moon,<sup>5</sup> using Miller's antigen, found that 85 per cent. of cases diagnosed clinically as tuberculosis gave a positive result, although 38 out of 100 Wassermann positive serums gave a positive reaction with his tuberculous antigen.

Other workers using antigens of this group have obtained similar results.

#### Group 2.

The best known of these antigens is Besredka's antigen. He has obtained a high percentage of positive results in definite cases of tuberculosis. But many other workers, including Inman,<sup>6</sup> Debains and Jupille,<sup>7</sup> and Bronfenbrenner,<sup>8</sup> have brought forward evidence to show that this antigen is not specific in that Wassermann positive serums may give a positive reaction when tested with this antigen. The work of the last named is of special interest.

It is well known that the complement-fixing substance in syphilitic serums is not an antibody specific to the spirochaete but a lipotropic substance, and this lipotropic substance may bind complement in the presence of lipoidal substances present in tubercle bacilli. Moreover, the addition of alcohol and other substances to tubercle bacilli may intensify this non-specific lipoidal action of tubercle bacilli.

Bronfenbrenner's experiments are complicated, but they appear to prove that the complement-binding substances present in tuberculous serums are specific antibodies to tubercle bacilli, and not lipotropic in character. In cases where a double infection with the *Spirochaeta pallida* and the tubercle bacillus was present he appears to have been able to demonstrate the presence in the serum of both the lipotropic substances due to the spirochaetal infection and also the specific antibodies to the tubercle bacillus.

In view of these facts it appears to us that a dilute suspension of tubercle bacilli in saline is undoubtedly the best antigen for this test. In such an antigen the lipoidal substances are not present in a sufficient amount to cause any fixing of complement in the presence of lipotropic substances, nor is there any alcohol or other substance added which would intensify this non-specific action. Another and very great advantage that it would appear to us that this antigen possesses lies in the fact that it is not to any appreciable extent anticomplementary. There can be very little doubt that many of the false positives that some workers have obtained have been obtained owing to their antigen giving rise to non-specific summation effects in virtue of slight anticomplementary properties.

#### Group 3.

Different workers have used various extracts and derivatives of tubercle bacilli as antigens. Calmette and Massol<sup>9</sup> have used water and peptone soluble preparations. Corper<sup>10</sup> used tubercle bacilli autolysed for ten days at incubation temperature in salt solution; Dudgeon, Meek, and Weir,<sup>11</sup> an alcoholic extract of tubercle bacilli; Wang and Chroket<sup>12</sup> tubercle bacilli heated with alcohol, ether, and chloroform; Wilson<sup>13</sup> an alcohol and ether extract dried and suspended in saline.

The remarks that we have made with regard to Group 2 apply with equal force to this group.

#### CAUSES OF DIFFERENCES OBTAINED BY DIFFERENT WORKERS USING THE SAME ANTIGEN.

The varying results obtained by different workers using different antigens is no doubt due in part to the difference

of the antigen. The differences obtained by various workers using the same antigen do not at first sight seem easy to explain. But a little consideration will, we think, show certain possible contributory causes.

1. In the first place, and especially in regard to antigens of Groups 2 and 3, it appears to us that the description of the methods of their preparation are often wanting in details, and are frequently impossible of constant preparation, so that it is often impossible to be certain that one is using exactly the same antigen as that employed by the author whose technique one is endeavouring to follow.

2. In their publications many authors do not give a detailed description of the technique they have employed. They mention the antigen they have used, but they do not give in detail any quantitative data of the other reagents used in the test. Now Dean<sup>14</sup> has pointed out that there is a definite favourable quantitative relationship between antigen, antibody, and complement. It is not surprising, therefore, that variable results have been obtained by various workers if the technique is not adhered to in every detail.

3. A third manner in which differences of opinion as to the exact reliability of the test may arise is through incomplete control of the cases on the clinical side and through the employment of incomplete and inaccurate classifications of the cases. In all our cases we have investigated, as far as lay in our power, most carefully the clinical aspect of the patients, and we feel that part of the success in the results we have obtained has been due to this very careful clinical control. As an instance of what we mean, Stoll and Newman,<sup>15</sup> using Wilson's antigen, state that 58 per cent. only of cases of definite pulmonary tuberculosis gave a positive result. But among their cases of definite pulmonary tuberculosis they include a considerable number of cases without tubercle bacilli in their sputum. Now, for the purpose of controlling a test for pulmonary tuberculosis the only definite criterion for a case of phthisis should be the presence of tubercle bacilli in the sputum, for there is no combination of symptoms and physical signs which is pathognomonic of tuberculosis and which cannot be simulated by other diseases.

4. Finally, there is one other point in connexion with the method of performing the test we have adopted which is of importance in explaining the high degree of accuracy attained by this method. This relates to the amount of fixation of complement necessary for the reaction to be regarded as positive. Having, as we believe we have, in a dilute emulsion of tubercle bacilli an antigen possessing no non-specific complement fixing properties, we might reasonably expect to be able to detect relatively small amounts of specific antibodies. There can be no doubt that in some cases of active pulmonary tuberculosis the antibodies are present in the serum in small amounts only. We have found that any appreciable inhibition of haemolysis in the presence of one and a half H.D. of complement as estimated by titration in the presence of antigen should be regarded as a positive reaction.

There is one point upon which nearly all workers appear to agree. No test is likely to give 100 per cent. degree of accuracy in all cases. In our series some 2 to 3 per cent. of definite cases of pulmonary tuberculosis have given a negative result. It is the very acute and advanced case which may give a negative result. Many other workers have found also that moribund cases may react negatively.

#### CONCLUSION.

We have tried to suggest some of the possible causes of the uncertainty which up to the present time has existed as to the value of the complement fixation test in tuberculosis. In spite of much contradictory evidence we think there has been a steady improvement in the method employed and the results obtained. The work that we have done appears to be in line with the work that has gone before, to which it gives merely the finishing touch.

more film-like. He wished to make it clear that thoracotomy was not attended by any appreciable pain, nor was it followed by any evil after-effects, except perhaps slight surgical emphysema in the region of entrance. The actual touching of the parietal pleura was definitely painful. The concentration should be done with the canter red hot, and at white heat, as the latter was apt to cause subsequent haemorrhage. One of the main objects of thoracoscopy was, therefore, the examination and adhesion of the band-like adhesion, preventing collapse of a cavity after the production of artificial pneumothorax; it was also of great value as a means of diagnosis, especially with regard to pleural and mediastinal conditions. He considered that concentration was contraindicated where tubercles of the pleura were present, even in the early stages, and was impossible where large surface adhesions were present. These were especially found at the apex. It would be seen, therefore, that there was only a limited field of usefulness with respect to concentration, but even the limited number of cases would justify the retention of this method of treatment. Thoracoscopy would also be found of increasing value as a means of diagnosis in selected cases of pulmonary, pleural, and mediastinal conditions of an obscure nature.

The second surgical method of treatment which he discussed was the production of collapse of the lung by means of operations on the chest wall. Attempts at partial collapse did not appear to be entirely satisfactory. He had no personal experience of apical pleurectomy, but the filling of the space created between the parietal pleura and the endothoracic fascia had offered some difficulty. Paraffin was appeared to act as a foreign body, and might require subsequent removal, whereas fatty tissue for purposes of filling was only obtained with difficulty. Introduction of gauze and subsequent healing by granulation could only result in the eventual adhesion of the separated layers and the re-establishment of the pre-operative relations; for this reason the latter method did not appear to him to hold out any hope of permanent benefit. With regard to thoracoplasty, the indications were practically confined to those cases where artificial pneumothorax had been tried without success or with only partial success. There was only one exception, and that was where artificial pneumothorax had been successfully carried out with considerable improvement over a long period, the disease was considered cured, and the lung had been allowed to expand. In such cases, if symptoms recur, resumption of artificial pneumothorax would be found impossible owing to generalized adhesions over the whole surface of the pleura, and further gas displacement was impossible. He had performed thoracoplasty in six cases up to the present—three for tuberculous, two for bronchitis, and one for pulmonary abscess. In the first three, one patient had definite extension to the opposite side, was confined to bed and was generally debilitated, with persistent vomiting and pyrexia. Artificial pneumothorax was impossible owing to the thickness of the pleura. Improvement was marked, with disappearance of the bacilli and an amelioration of all symptoms. This was maintained for some months, but he had heard recently that the condition was now less satisfactory. The second case was a young man with marked symptoms of advanced disease and in a state of extreme debility. The operation was only 90 mm. systolic, and the temperature was high and inverses in type. The actual operation was followed by death in two hours. The third case had only recently had the first stage completed. The outlook was definitely more favourable, attempts at artificial pneumothorax were not successful, and the patient had been confined to bed owing to high fever on movement. The blood pressure in this case was measured before operation, and was found to be 121 mm., and the pulse rate 140. At the completion the pressure was 119 mm. and the pulse rate unchanged. With regard to biopneumothorax, in one case only lower half thoracoplasty was done several months

before, with decided benefit up to the present. The other, in which complete decompression was performed with a more than temporary improvement, but there was involvement of the opposite lower lobe. The point he wished to bring out very strongly was that unless the operation was performed at a reasonably early period of the disease it could not be hoped in this country to get from these measures the results which were being obtained on the Continent and in America. The operations, when done under local anaesthesia and in two stages, were accompanied only by a minimum of shock. There was one exception, and that applied more especially to cases of bronchiectasis. Shock arose from the change of position of the mediastinum, in the absence of pleural adhesions, and was shown chiefly by cyanosis and some dyspnoea. It was well illustrated by the two cases of bronchiectasis described. The one, where adhesions were present, showed no disturbance following the rib resection, whereas the other, with a free pleura, became cyanosed and dyspnoeic at the same stage, a condition which persisted in a modified degree for the ensuing forty-eight hours, but was eventually followed by the better result. All the cases had been done in two stages posteriorly, the lower ribs (5 to 11) in the first, and the upper four, including the first rib, after an interval of not more than three weeks. Local anaesthesia was invariably used. Pneumothorax has been performed five times, either by direct division of the nerve, by crushing, or by direct intraneural injection of alcohol. He considered this measure to be comparatively little value alone, and rarely required when the major operation was performed. He hoped that in the course of time these procedures would become more generally adopted in this country, as they were abroad. There was no doubt that they had passed beyond the experimental stage, and in the state of our knowledge to-day they offered a distinct advance in the treatment of certain forms of pulmonary tuberculosis.

Dr. CLIVE RITZKE (London) said that they had become so accustomed to look to Vejleborg Sanatorium for sound and progressive work in tuberculosis, that Dr. Gravesen's opening address seemed bound to strike, as it had, the right note. One or two comments he was tempted to make, although his views were mostly in agreement with those Dr. Gravesen had expressed. First, in regard to the partial pneumothorax and cannulization of adhesions, in view of his experience he found it hard to believe that the partial pneumothorax need give such unsatisfactory results as those shown in Sæugman's well known statistics, and he wondered whether others could be found to agree with him in this. The great trouble with such partial pneumothoraxes was the recurrence of large reactions after the intercal and other methods, then certainly the pneumothorax was doing more harm than good. But in cases where this difficulty was overcome he had obtained much help from pneumothoraxes far from complete. They were then the means of turning diseases to more chronic lines, and where a pleurisy also supervened they might initiate healing fibrosis in an otherwise hopeless lung. He had sometimes wondered whether, in some of these cases, notifiable for more than this, the cannulization of pleural sinuses by injection of 50 per cent. dextrose, as was used by Spengler under other conditions, might not be a useful measure. In regard to cannulization of adhesions, it seemed to him that there were extremely few cases where this measure was really indicated. When he saw cobwebs' radiograms he was struck with the belief that these cases were all under a low intrapleural pressure, and that many of the adhesions would have stretched, without need of a reasonable increase—perhaps  $\frac{1}{2}$  to  $1\frac{1}{2}$  cm. or so. On inquiry, it proved that this was so—that the pressures used had been low ones. The slightest of a few strong adhesions would have seemed of great benefit, had often possessed diaphragmatic adhesions, and Jacobsen appeared to have had little success in that case. There was, as Dr. Gravesen remarked, a

the clinical diagnosis was confirmed either by *post-mortem* examination or by finding tubercle bacilli by microscopic examination. All of them were more or less pathological fluids, but none showed more than a trace of turbidity. With two exceptions the patients were all children.

TABLE II.—Cerebro-spinal Fluid: Tuberculous Meningitis.

|                 | Positive. | Negative. | No. of Specimens. | Percentage of Positives. |
|-----------------|-----------|-----------|-------------------|--------------------------|
| Wang ... ..     | 13        | 5         | 18                | 72.2                     |
| Besredka ... .. | 5         | 12        | 17                | 29.4                     |

This table does not enable a comparison to be made between the properties of the two antigens, as the specimens were not all tested with both. The results given with seventeen specimens tested with both are shown in Table III.

TABLE III.—Cerebro-spinal Fluid: Two Antigens.

|                 | Positive. | Negative. | Percentage of Positives. |
|-----------------|-----------|-----------|--------------------------|
| Wang ... ..     | 12        | 5         | 70                       |
| Besredka ... .. | 6         | 11        | 35                       |

In six instances Besredka gave negative and Wang positive results. In all cases where Besredka gave a positive Wang was also positive. Thus it appears as if Wang were the better of the two for testing cerebro-spinal fluid.

**Cerebro-spinal Fluid Controls.**—The cases for which these specimens were obtained included acute and chronic conditions with no evidence of tuberculosis, cerebro-spinal fever (1), meningo-encephalitis of doubtful nature (1), encephalitis lethargica (1), septic throat with meningeal symptoms (1), cerebral tumour (1), uraemia (1), meningococci (1), hydrocephalus (3), and some other conditions of doubtful nature.

TABLE IV.—Cerebro-spinal Fluid: Controls.

|                 | Positive. | Negative. | Total. |
|-----------------|-----------|-----------|--------|
| Wang ... ..     | 7         | 13        | 20     |
| Besredka ... .. | 2         | 14        | 16     |

Sixteen specimens were tested with both antigens, and of these there were three in which Wang was positive and Besredka negative. In every instance where Besredka was positive, Wang was also positive. Apparently Wang is liable to give more fallacious reactions than Besredka.

## REMARKS.

Complement fixation tests in tuberculous constitutions have been the subject of much study and many workers have found the test to be of high diagnostic value. In concluding my previous communication I said I was not satisfied that complement fixation tests afford a reliable means of clinical diagnosis in tuberculous cases, and I remain of the same opinion. The reaction is a specific one in the sense that under certain conditions the mixture serum *plus* extract will fix more complement than either of two alone, but it seems clear that the property of fixing complement in the presence of an antigen derived from tubercle bacilli is shared by serums from cases other than cases of tuberculosis. A positive result does not necessarily mean a definite tuberculous infection. Probably the number of such false diagnostic reactions is not large, but the fact that they occur must not be ignored. One of the chief aims of the present work was to see whether Besredka was better than Wang, and the results are encouraging. The results with control specimens of cerebro-spinal fluid were disappointing.

## Prognostic Value of the Test.

Through the kindness of Mr. Telford, some observations were made on the prognostic value of the test. The patients

were children aged 6 to 15 years, inmates of the Swinton School for Crippled Children under treatment for various forms of chronic tuberculosis of spine, hip, and knee. They were under close observation for long periods, and it was possible in twenty-nine instances to make two tests with two antigens on each occasion. The specimens of blood were collected by the matron of the hospital, Miss M. Draper. The first series of tests were made between November, 1921, and February, 1922, and the second during the latter part of 1922. In July, 1922, and March, 1923, Mr. Telford made a special clinical examination of the children and stated in each instance whether the progress of the case had been good or bad. In giving his opinion he was guided by such clinical evidence as seemed of importance in the light of his long experience of such cases. There was usually something definite, such as abscess formation or loss of weight, to help him, but in some instances it was difficult for him to make a decision. The terms "good" and "bad," therefore, must be interpreted liberally—that in his opinion as surgeon the progress had been more or less satisfactory. The results given by the two antigens were not always in agreement. Every patient gave at least one positive reaction with one or other of the antigens on either the first or second examination. The following table shows the results obtained with each antigen, the number of positive and negative reactions, and the number of cases in which the progress in the period intervening between the collection of the sample of blood and the time of clinical review had been good or bad.

|          | First Series.      |                           |                    |                           | Second Series.     |                           |                    |                  |
|----------|--------------------|---------------------------|--------------------|---------------------------|--------------------|---------------------------|--------------------|------------------|
|          | Positive Reaction. |                           | Negative Reaction. |                           | Positive Reaction. |                           | Negative Reaction. |                  |
|          | No.                | Progress.                 | No.                | Progress.                 | No.                | Progress.                 | No.                | Progress.        |
| Wang ... | 9                  | Bad 1<br>Good 8<br>(88%)  | 20                 | Bad 6<br>Good 14<br>(70%) | 21                 | Bad 5<br>Good 19<br>(20%) | 5                  | Bad 0<br>Good 5  |
| Besredka | 18                 | Bad 2<br>Good 16<br>(88%) | 11                 | Bad 5<br>Good 6<br>(4%)   | 13                 | Bad 5<br>Good 14<br>(26%) | 10                 | Bad 0<br>Good 10 |

Apparently a positive reaction in a case of active tuberculosis is more favourable as regards prognosis than a negative, but where there are no signs of active tuberculosis a negative result points to a healed tuberculosis. A negative reaction followed by a positive indicates that improvement is setting in. These points are shown in the following diagram, which shows the number of instances where the reaction was unchanged or changed. The figures above the short horizontal line are "progress good" and below it "progress bad." The figures to the left relate to antigen Wang and to the right to antigen Besredka.

| Positive Unchanged. | Positive to Negative. | Negative Unchanged. | Negative to Positive. |
|---------------------|-----------------------|---------------------|-----------------------|
| 6    9              | 3    9                | 2    1              | 13    6               |
| 0    0              | 0    0                | 0    0              | 4    4                |

The number in the various categories are small and it is unsafe to draw conclusions from them. The three cases included in "negative unchanged" were very slow chronic cases, and on first clinical examination in July, 1922, were progressing badly. They subsequently did better and were probably healed at the time of the second test.

On the whole it cannot be maintained that the indications furnished in this work as regards prognosis could have been of any great assistance to the clinician.

## REFERENCES.

- <sup>1</sup> Sellers and Ramsbottom, *Journ. of Path. and Bact.*, vol. xxv, 1922, p. 427. <sup>2</sup> Wang and Crockett, *BRITISH MEDICAL JOURNAL*, 1919, ii, p. 7. <sup>3</sup> Besredka, *Ann. de l'Inst. Pasteur*, tome xxxv, p. 291.

might well be questioned, to say the least of it, and which will tend to rouse rather than allay the groundless fears, not only of the general public, but of the less instructed members of our own profession. But he did say:

"If the patient were properly trained as to his habits and carried out the medical instructions, and if full regard were paid to ventilation, sunlight, cleanliness, removal of dirt and dust, and the like, then risk of infection might not be so serious as to those who resided with him. Still less was the risk to those who entered the house after the patient had left it proper methods of disinfection had been adopted."

It is to be regretted that there is no recognized standard either legal or medical, of what constitutes proper disinfection. I should like to say here that it is within the power of a tuberculous person in all except the very latest stages of the disease to keep himself from being a danger to the community.

The question of how a given case has contracted tubercle is very difficult to answer. In a report of 572 cases treated in 1913 and 1914, published by me in 1915, in only three could the actual source of the disease be given with any degree of certainty. In one case a girl caught it from a friend with whom she was living, and to whom she was devoted; in another, a man—a valet—caught it from his master; and in a third, a girl—a lady's maid—caught it from nursing her mistress. In all these cases the exposure was both intimate and prolonged, and the soil—the other great factor—most receptive. There can be no doubt that this latter element—the soil on which the seed falls—is really the more important of the two, though it is extremely elusive and difficult to tackle. We can only speak of it in vague terms, such as predisposition, "run-downness," health, anxiety, selective attraction, and so forth; but still it is there, and it is a very potent factor in the contraction of the disease.

But if tuberculosis is as widespread as we have reason to think it is, how is it spread? There are two great theories at present holding the field:

1. The dose to be effective must be a massive one—that is, it must be a really knockdown dose—and, I personally should add, it must be intimate and

2. The attack depends on the virulence of the bacillus.

But in considering these two theories we must not forget the great second factor in the case—the pre-disposition to which we have just referred.

Now these two theories are really untested, although as far as one can judge the evidence in favour of the former theory is very much the greater. A patient of mine—a clergyman—about twenty-two years ago, spent a very hot August in London, visiting every day an East-end woman suffering from advanced consumption. Open-air treatment in that district and at that time was conspicuous by its absence. He was run down, wanting his holiday, and he contracted tuberculosis of the lungs. His dose must have been a very big one, because the incubation period of the disease was so short, and he came into my hands the following February. He had an excellent constitution, had always had good health and been very well fed, but he had a most tremendous struggle for life. He was in bed for eighteen months with a high temperature, and with such heavy night-sweats that often the mattress was wet through and the wires below it rusted. But he ultimately recovered, and for the last fifteen years has had a parish in a big town in South Africa.

The second theory has been more recently brought forward, and the work on it is by no means concluded. Indeed, with regard to work on tuberculosis in general, in spite of all that has been done and the public attention that has been directed to the subject, there are many things, as I have stated above, which are still left undecided. It may be that as long as the disease exists this will always be so, and that to the very end opinions will be divided as to the causes even of its final disappearance. Indeed, this possibility can hardly be wondered at, considering the universality of the proposition. Ever since the discovery of the tubercle bacillus by Koch in

1882 there has been before us the possibility of a general immunization of the human organism, in the same way in which one attack of scarlet fever makes the subject immune to another attack, so it has been thought that by giving a small dose of the disease might have the effect of stopping a large dose later on from resulting in a definite evidence for this theory. Some people have gone so far as to say that in early childhood immunity is conferred by the taking of milk with a small number of tubercle bacilli in it, and have wondered whether the milk campaign at this stage may not do more harm than good. I hardly like to refer to this in an assembly of this kind, but if it be true that the bovine bacillus protects from the human bacillus later on in life—and again there is a good deal of evidence in support of this—it ought at least to be mentioned. Personally I think we ought to go on getting our milk better and better, and that a clean milk campaign is a very good one and ought to be encouraged in every way in our power.

With regard, however, to the possibility of contracting tuberculosis to the extent of its being a serious illness, dose and on the exposure being intimate and prolonged. Moreover, in cases suspected as being from milk, the infection has often come from the milkers and other people dealing with the cows rather than from the cow. What ever seems uncertain—and I must confess a great deal!—still unsettled—the fact that tuberculosis can be conveyed from person to person is undoubted. How this is done, and by what channels it is admitted, whether it is inhaled or taken in by the mouth, is still hotly contested.

The really cheering thing is that tuberculosis is going down. Why is it going down? Here again opinions differ; some say one thing, and some another, according to the way the problem is presented to them. The sanitarian reformer thinks it is drains; others think it is housing; others, again, think it is work by health activities of various sorts—wellfare centres, etc.—whereby people are better educated. Others, again, think it is the formation of sanatoriums and the whole scheme for better called the "dispensary scheme," or the "Edinburgh scheme." It is possible that all these different agencies have helped—improved sanitation probably; housing certainly, although there are several points that are emerging which seem to show that overcrowding even is not quite so responsible for cases of tuberculosis as we thought it was. For example, whether people live in one room or in six, as far as Glasgow is concerned, does not appear to make much difference in the incidence of tuberculosis. Again, as we have seen, tuberculosis in women went up very considerably during the war; women were employed in munition works and other factories—in other words, they largely became an industrial population on a par with men. Tuberculosis is without doubt largely an industrial disease, as is evident when we realize that the recorded mortality in men from 45 to 75 from this disease is twice as high as among women. There is also, as we have already noted, one more point as to the rise of mortality from tuberculosis in women during the war—they may have had less good and suitable food, for the mortality amongst children went up too. With regard to sanatoriums and dispensaries, this whole method has been most unfairly criticized and derided. In the first place, what this whole campaign did was to focus public attention on the immensity of the whole problem. Possibly this was done not wisely but too well, especially regarding it as no more infectious than a wooden leg, to looking upon it like measles and scarlet fever. Still, a great amount of good in treating a very large number of people with tuberculosis and in curing a very large number of people who would otherwise have been lost to the community. And we must never forget that tuberculosis is a disease that has attacked men and women of great

between the lamps is 0.6 metre, measured between the carbons, and the crater on the positive carbon is 1 metre from the ground. The patients are sitting round the lamps. Should we have to treat patients who cannot support a sitting posture, we make use of three 20-ampère lamps hanging side by side; the space between the lamps is 0.55 metre, measured between the carbons; the crater on the positive carbon is 30 to 35 cm. over the couch of the patient.

The 75-ampère lamps, of course, are radiating much more chemical light than the 20-ampère lamps; but at the same time the heat rays are increased considerably and consequently one can get much nearer the 20-ampère lamps than the 75-ampère ones.

The intensity of light decreases with the square of the distance; if the patient, therefore, is 1 metre from the light crater, he gets only a quarter of the light that he gets if the distance is 0.5 metre. You will understand, after my remarks about the heat rays, that we can assess the difference in the light intensity between the two installations by placing the patient nearer the light itself.

Around the 75-ampère lamps from six to eight patients can sit at one time, and by employing the 20-ampère lamps we can treat two patients in a reclining position at the same time.

If one wished to have patients in a reclining posture treated by the big lamps, one could have only two patients; for if a greater number were to be treated at the same time one patient would merely shade the other. Thus it is more economical to apply the 75-ampère lamps, if one has many patients who are able to assume a sitting posture, and the 20-ampère lamps if one is treating patients who have to be in a reclining position.

I shall now review the diseases we treat.

#### I. LUPUS VULGARIS AND OTHER FORMS OF SKIN TUBERCULOSIS.

The local application of concentrated light in the treatment of lupus vulgaris, introduced by Finzen, was an entirely new therapeutic principle. The aim was to attack from outside the diseased tissue without injuring at all the healthy tissue, and experiments showed that the concentrated light produced a proliferation of the healthy tissue, bringing about a new formation of vessels, and at the same time destroying the diseased cells. It was shown to be a considerable advance in the treatment of lupus vulgaris. This disease was really, in a large number of cases, incurable, and those of the patients who were cured remained disfigured with ugly scars. The majority of these patients are now cured by Finzen's local light treatment, leaving only smooth and almost imperceptible scars.

A vast collection of material shows, in our experience, that over 60 per cent. of cases were cured. Dr. Sequeira, of the London Hospital,\* one of the first to make use of the treatment, has had 70 per cent. of permanent cures; he is of opinion that we have had under treatment a graver type of lupus than he has had in the London Hospital. The results of the treatment of tuberculosis verrucosa and tuberculosis colliquativa have been even more excellent (80 to 100 per cent. cured).

The value of the local application of concentrated light is, of course, incontestable, but we have long recognized that a certain number of cases are refractory to the treatment, and in other cases the disease has a tendency to increase too rapidly to be dealt with adequately by this local treatment, or, if apparently cured, is likely to relapse. Finally, some cases are so advanced before treatment that they already have a bad prognosis.

In these cases I decided first to try the carbon arc-light baths, and the results were better than I expected. I succeeded in curing 96 patients out of 114 by the combination of local light treatment and light baths—cases which had failed to be cured by the local application of concentrated light, notwithstanding that they had been treated very energetically. On examining the figures now, where

patients under treatment for lupus vulgaris are getting local light treatment and light baths simultaneously, I find that the proportion of permanent cures is about 90 per cent. The enormous value of light baths in the treatment of lupus vulgaris is evident from the fact that not only are the results getting much better but also the time devoted to curing patients is getting much less.

One might ask whether light baths alone are not able to cure the patients; but I can assure you that however invaluable the light baths are in the treatment of lupus vulgaris, so indispensable also is the local Finzen treatment. No doubt a single little spot can disappear by the light bath, but it is very rare. The disease can be improved by light baths alone, but a real cure will not occur without local application of concentrated light.

I would now like to show you some illustrations of patients before and after treatment. (See special plate.)

#### II. SURGICAL TUBERCULOSIS.

Simultaneously with the light bath treatment of lupus vulgaris, I have also tried the effect of carbon arc light on different kinds of surgical tuberculosis, and I have asked the consulting surgeon in our institute, Dr. N. P. Ernst, to examine and to control these patients.

During a period of eight years (1913-1921) we have treated no fewer than 439 patients by carbon arc-light baths—145 with uncomplicated closed cases of surgical tuberculosis and 294 complicated with sinuses or abscesses. The results have been most excellent, according to the accompanying table taken from the late Dr. N. P. Ernst's latest report (*Acta Radiologica*, vol. i, 422).

In the table you will find the cases more numerous than the number of patients, for many of the patients were suffering from two or more diseases at the same time. The value of percentage of cures is increased owing to the fact that almost all cured patients are observed for several years after their cure. I would also draw your attention to the fact that a great number of the cured patients have regained free mobility of their joints.

If you would judge the results obtained by the application of carbon arc-light baths in the treatment of all these patients, it is necessary to remember that our patients are mainly adults (70 per cent. were more than 15 years of age), and you know that tuberculosis in adults is more difficult to cure than in the case of children. It should be remembered also that many of our patients, owing to lack of space in the institute, have had to be treated as out-patients, and during the light treatment they have lived in their own homes, which are often very poor and unhealthy. Daily, or every other day, they have had to be transported to the institute, and you will very well understand that this moving about has not benefited them. Finally, it must be emphasized that many of our patients, especially those with pelvic osteitis, hip disease, and spinal caries, have been suffering for so many years that one could not hope for recovery, but we considered it our duty to make an attempt.

The results obtained by application of carbon arc-light baths in the treatment of surgical tuberculosis are brilliant. To give an idea of the value of the results obtained by us I should like to make a comparison with the results obtained by Rollier, calling to mind, however, that he is working under much more favourable conditions with his patients inside his hospital. I take the figures from Rollier's *La cure de soleil*, 1915.

**Ankle-joint.**—Of 94 cases, complicated and non-complicated, Rollier registered 87 (92 per cent.) as cured, but under tuberculosis of the ankle-joint he includes cases of osteitis in the calcaneus, tarsus, and metatarsus, which have a far more favourable prognosis than those which Dr. Ernst includes—namely, tuberculosis round the astragalus. Of the 47 cases which Ernst includes among ankle-joint tuberculosis, we have cured 42 (89 per cent.), and 36 of these cured patients have regained complete mobility of their limbs.

**Tuberculosis of the Elbow.**—The proportion of cures by Rollier is 66 per cent.; we have to record 83 per cent.

The results we have had in treating different forms of surgical tuberculosis are at least as good as those obtained by heliotherapy in mountain heights.

\*After this paper was written I read Dr. Sequeira's paper, "Carbon arc-light baths in the treatment of lupus vulgaris" (*Brit. Journ. of Dermatology*, March, 1923). I am quite in agreement with Dr. Sequeira in the views therein stated.

*What Conclusion can now be Drawn from the Results  
Obtained by Treatment with Artificial Chemical  
Light Baths at the Finsen Institute?*

First, we learn from the results by Rollier and in the Finsen Institute that non-operative treatment ought to be used in cases of surgical tuberculosis, not only in children, but also in adults, as Sir Henry Gauvain put forward in the *Lancet* in 1921 (i, 1065), when he published the brilliant results obtained by him at the Treloar Cripples' Hospital and College at Alton and Hayling Island. Secondly, we learn that the most important factor in the conservative treatment of surgical tuberculosis in the mountains is the powerful light to be had there; many of the patients treated at the Finsen Institute, however, have been living under very poor hygienic conditions, and despite this fact they have recovered.

What I have said on this point is not to be understood in the sense that we should not obtain better results if we made use of all factors which we have in the mountains or at the seaside—namely, the crisp air devoid of mist, the benefit of sea baths, etc. Particular stress must, however, be laid on the light, and in the sanatorium at the seaside and in the mountains there should be artificial sources of light for light baths for the times when the sun cannot be utilized, for then the results would be much better and the time spent on the treatment of less duration.

Conservative treatment of surgical tuberculosis is not to be understood in the meaning that operative treatment must never be employed—that is not the correct definition, for it happens very often that abscesses have to be aspirated and sequestra have to be removed. The correction of ankylosis or other deformities is indispensable, and if a case does not improve it may be necessary perhaps to extirpate the tuberculous lesion.

All these facts have been so well described by Sir Henry Gauvain, that it is superfluous to go further into the matter here. Furthermore, I would like to emphasize that in addition to the light it is of utmost importance to make use of all the adjuvant and auxiliary methods known to us in treating surgical tuberculosis. I shall only emphasize the enormous importance of orthopaedics, and concerning the rest I would refer you to Sir Henry Gauvain's papers to be found in the *Lancet* and the *British Medical Journal* (November 26th, 1921, p. 876).

*How are we to Explain the Effect of Light on  
Tuberculosis?*

I regret to say we have not advanced any further in our knowledge of this question than did Finsen in his day. Light gives an erythema of the skin, followed and accompanied by pigmentation, and light has a stimulating effect on the organism in general. The results are obtained only clinically, and conclusions must be drawn by clinical results alone. Not that explanations and experiments are wanting, but these are merely hypotheses. I shall therefore not touch on this point, but try to find out what is to be learnt by clinical experiences.

In the treatment by heliotherapy of cases of surgical tuberculosis we obtain by far the best results in the mountains or at the seaside, while the results in low-lying inland regions are less favourable. From this fact we must conclude that the chemical power in the sunlight is of great importance to the treatment, for the atmosphere absorbs the chemical rays, and the more compact the atmosphere is, the greater is the absorption. The chemical power of the sun is therefore much less in lowland districts than in mountain heights; at the seaside the lesser intensity is compensated by reflection of light from the mirror surface of the sea, by which the intensity of light is increased enormously. This shows us that for good effects the chemical power of light is decisive.

*What Kind of Chemical Rays are in Question?*

On this point we know but very little. We are aware, however, that the atmosphere especially absorbs the ultra-violet rays; these therefore must be the most important, and especially the ultra-violet rays with long waves, for the thinnest layer of the atmosphere absorbs all rays with short

waves. A series of investigations (Jansen, Maar, Hasselbalck) shows us that the greatest importance must be placed on the ultra-violet long wave rays; these alone have the power of penetrating the epidermis. The violet, blue, and green rays are also of a certain value, as Finsen's experiments have shown; and recently Sonne claims that not only these rays, but also the green, yellow, and luminous red rays are of importance, according to experiments made by him in the Finsen Institute.

*What Kind of Illumination is to be Preferred?*

Naturally the sun is the best and the most economical source of light, when it can be used. As mentioned already, the atmosphere absorbs a great deal of the chemical light of the sun; the absorption increases in proportion to the thickness of the atmosphere—in other words, it is greatest in lowland countries. Furthermore, the less perpendicular the rays are, the greater is the absorption from the atmosphere, because the length of the rays, passing through the lower and more concentrated regions of the atmosphere, increase as the rays fall less and less perpendicularly. The chemical force of the sun is, therefore, considerably greater in the mountains than in the lowlands, though I must emphasize once again that at the seaside the light intensity is increased very considerably by the reflection of the mirror surface of the sea.

In the mountains the sun can be used during the greater part of the year, but in the lowlands only when the light is falling rather perpendicularly—in Northern Europe, for example, only in summer, and, of course, in bright and clear weather. In the mountains as well as in the lowlands artificial illumination should be employed during the absence of sunlight.

*What Kind of Artificial Light Sources are to be Used?*

Practically we have only two sources that contain a quantity of chemical light, worth mentioning—namely, the carbon arc light and the mercury-vapour arc light. The difference between these two kinds of lights is in reality very considerable. The carbon arc light contains all the rays of the spectrum, while the mercury light mainly contains the ultra-violet and particularly the short-waved ultra-violet rays, with but slight power of penetrating. Referring to my previous remarks on this subject it is evident that the carbon arc light is without doubt more suitable for light baths than the mercury light.

In a series of experiments undertaken at the Institute I have proved that far better results are obtained with the carbon arc light baths than with mercury light baths. In Germany the mercury light has been used most, and lamps have been constructed called *Künstliche Höhensonne*—a name that is, in reality, quite misleading, as the "high sun" contains all kinds of rays, while the spectrum of the mercury light is strongly limited, and has the maximum in the ultra-violet rays, especially those with short waves. Naturally the mercury light has some effect, and if the carbon arc light, on account of deficiency of current, cannot be employed, the mercury lamps, especially the new Jesionek lamps, are of some value; but we must not expect to obtain approximately such favourable results as with the carbon arc light.

Because of the one-sidedness of the mercury light, an attempt has been made to supply the qualities of the missing rays by using strong incandescent lamps constructed with metal wire for irradiating simultaneously with the mercury light; but it has not been possible to create a source of light proportionately equal in value to the carbon arc lamps such as I have described.

*How Long and How Often are we to Irradiate  
the Patients?*

As has been mentioned, chemical light produces an erythema of the skin, stronger or slighter according to the time irradiated. Rollier is of opinion that strong erythemas are to be avoided, but I do not agree with this view, for I hold that the best results are obtainable with the carbon arc light if a pronounced erythema is produced in the earliest stages of the treatment. Consequently, the first light bath which a patient gets is of

Dr. G. BROOKES DIXON (Birmingham) said that there could exist no reasonable doubt as to the infectivity of tuberculosis since Koch's discovery. Unfortunately the factors were so variable, so complex, so difficult to appreciate in their entirety that we were prone to accept in abstract whilst to some extent ignoring them in practice. The extent of infection was shown by the tuberculin test; in Paris, Vienna, and Prague the test was positive in 55 per cent. of children aged 5 years. The possibility of infection was shown by the examination of clinical records. In Birmingham, of 7,547 children there were 2,664 who possessed fathers, brothers, mothers, or sisters who were known to have died from or to be suffering from tuberculosis. The fathers or brothers amounted to just over 10 per cent.; the mothers or sisters were about equal, and wives affected in a figure just over 8 per cent. The amount of fatal disease resulting from infection could be more or less accurately measured by the mortality rates, which in European countries varied for tuberculosis between 7 and 19 per cent. of the total mortality rate. Fortunately between the numbers who are known to have suffered infection and those who died from tuberculosis there was a large discrepancy, represented by those who suffered more or less damage from their infection and its resulting disease. One of the main difficulties to-day was that we had no stabilized or completely known as to what were the factors which determined whether an infection would have a benign and protective

gested by the figures for New York City:

| Year. | Deaths. | Deaths from pulmonary tuberculosis per 100,000. |
|-------|---------|-------------------------------------------------|
| 1937  | 3,350   | 229                                             |
| 1914  | 5,151   | 175                                             |
| 1921  | 6,474   | 22                                              |

Compulsory segregation was not advisable, but the possession of compulsory powers was useful. Because they were not enforced was no argument as to their failure. There was no intention to enforce them frequently, but rather to educate public opinion and reinforce the argument in getting patients to accept a prolonged period of treatment in their own and others' interests. The best defence against bovine infection was the treatment of milk in such a way before sale as to render any tubercle bacilli present inert.

| Year | Dads. | Percentage of total population |
|------|-------|--------------------------------|
| 1907 | 3,300 | ...                            |
| 1914 | 8,151 | ...                            |
| 1921 | 9,474 | ...                            |

infection, there was an accumulation of evidence which suggested that this existed within the first half-decade of life. The question was asked, How did infection from human sources occur? Infection with human tuberculosis was acquired from (1) sputum and its spray; (2) intestinal excretion (Williams), (3) the urine of tuberculous patients (Burnard), (4) from the milk of nursing mothers (as shown by Delphine Lamada in Japan); it was also asserted that (5) it might be conveyed by living carriers, a point, it was suggested, which might be undertaken by mice. How then, he asked, might infection be guarded against? In this connection attention should be directed to both human and bovine sources of infection. Infection from human sources might be controlled (1) by the adoption of measures designed to protect individuals who were exposed during the period when they were most susceptible—that was, during infancy and early childhood; and (2) by activities directed to the supervision and control of known sources of infection. The protection of infants and young children, as exemplified by the Granicher system in Paris, had given excellent results. It was based on the assumption that tuberculosis was not acquired by heredity, but by contact, especially during infancy. It was asserted that most infants of mothers who became infected, whether breast-fed or not; the danger was said to be the same if the father or another member of the family had open tuberculosis. Armand-Delille quoted the history of 150 tuberculous families, and showed that when the children remained at home with infected relatives the tuberculosis mortality rate was 60 per cent., and the tuberculosis mortality rate 40 per cent. Amongst 2,500 cases removed from infection by the Granicher method the mortality rate was 0.5 per cent., and the mortality rate 0.01 per cent., showing a striking difference between similar rates for children not removed from the source of infection. The Granicher method might be difficult to inaugurate in England; parents there were unwilling to give up control of their children. The excuse for leaving children exposed to infection. Particularly advanced tuberculin injections for infants under these conditions. It was simple, practical, economical, and so far free from complications and accidents. Measures for the control and supervision of known sources of infection might take the form of (1) education of patients and their contacts; (2) arranging for some segregation in the home by the supply of beds and bedding—there were now over 700 in Birmingham, and 200 sleeping shelters; (3) by providing a larger number of beds in institutions for the accommodation of advanced and chronic cases. Comment was to the education of the patient was unnecessary. Institutional accommodation should be provided (1) for treatment, (2) for education, and (3) for alleviation; in addition to exercise a measure of protection over the family by rearranging the physical strain, removing the centre of infection, and relieving the economic pressure. More beds usually meant a longer period of stay, and segregation was practised unobtrusively. Possible there was more than a casual relationship between the number of beds provided for tuberculous patients and the death rate, as was suggested.

TREATMENT OF TUBERCULOSIS BY SPÄHLINGER'S METHOD.

He suggested that the enormous rise of heart disease in New York since 1910 reflected the tendency on the part of practitioners to shield their patients from the disabilities of notification.

Dr. R. ROBERTSON (Vernon, Isle of Wight) said that the question which seemed complex had resolved itself in the course of the discussion to the need of an unlimited purse under the control of the medical profession.

Dr. R. A. YORKE (London) added his tribute to the admirable opening address of Dr. Jane Walker. He emphasized the importance of the social aspects of the disease, referred to by her—namely, poverty, infection, home conditions, family care, after-care, and occupation. He gave it as his opinion that the social measures suggested would seem to be the most important in the control of the disease, but he thought the last would be with the bacteriology, although the gaps in our knowledge were largely in the biology of the tubercle bacillus and in the immunity responses of the human body to it.

# TREATMENT OF TUBERCULOSIS BY THE

Dr. CLAUDE LITTLESTON (Gorleston-on-Sea) pointed out, with regard to the notification of tuberculosis, that so long as his patients were more built than blessed by nature, he felt tempted to label his cases as "heart disease."

STÄHLINGER METHOD.  
BY  
LEONARD WILLIAMS, M.D.,  
LONDON

In the cases whose details are given below I had the

Class 4.

diagnosed six months previously. When first seen, in January, 1914, he had cough, expectoration (tubercle bacilli present), night sweats, signs of induration at chest, loss of voice, sore throat. Signs of induration at

January, 1914. In May, 1914, the larynx was much improved and

Case 5.  
A. W. A case of tuberculous epiglottitis who received a short

cause of spinal tuberculosis. He was examined in 1920 for another complaint and there was then no evidence of active tuberculosis.

Case 6.  
A. T., aged 19, seamstress: comes from tuberculous stock (two brothers and two sisters died of pulmonary tuberculosis). History

resent 60 per field), emaciation, slight parestia, clubbing. Signs of

patient was commenced in December, 1914. After a six months' course of injections, during which the patient was able to continue her work, there was no evidence of active disease. Discharged. In

There is no trace of active participation in the process and no treatment since June, 1975, and is doing a full day's work.

E. G. woman, aged 29. First seen in November, 1913, on her return from a sanatorium where she had been for nine months. complained of glands in the right side of neck, for which an opera-

on had been strongly urged, a large number of patients had been given a course of Spallinger's vaccine. To the first five injections there was no reaction. To the

Thereafter the glands began to diminish and in three weeks had disappeared. The disappearance of the glands was accompanied by a striking general improvement. She has remained perfectly

and cough. Improved after residence in country. In 1913 he became  
orse; tubercle bacilli found in sputum. Tuberculin injections  
ere followed by violent reactions. When first seen, in December,

It, he had cough, expectoration (abundant green purulent sputum), pyrexia, haemoptysis, emaciation ill, night sweats, in chest, clubbing. Patient complained of

upper lobe with softening at apex. Spaulinger's vaccine treatment as commenced in December, 1914. In May, 1916, there was no evidence of active disease. Discharged. Died of influenza in 1918.

CASE 9.  
H. D., woman, aged 41, teacher; comes from tuberculous stock.

1901. Went to sanatorium—no marked improvement. Sent to another Swiss sanatorium for four years, whence she returned slightly improved but still coughing and expectorating a good deal.

F. B., aged 55, seamstress. History of haemoptysis eighteen months ago. Tubercle bacilli present. Had been treated at sanatorium. When first seen, in July, 1915, she suffered from cough, expectoration (tubercle bacilli present) to a moderate degree, dyspnoea, loss of weight, anorexia, night sweats, and signs of both upper lobes. Spitting up of blood, 100 cc. in January, 1914. In January, 1914, the chest was dry, and temperature and pulse normal. Treatment stopped. She had a short course of vaccine in April, 1914. In May, 1914, there was no evidence of active disease and no tubercle bacilli. Discharged.

For the cases whose details are given below I had the advantage of being associated with Drs. Dudley Kennard, Ernest Griffin, N. S. Board, and A. F. Bouchage. As the cases speak for themselves I refrain from comment. Many of these patients have often been collected, and could be collected again, for purposes of demonstration. Cases 17 to 23 have been treated with partial sera only, which were prepared in 1919-20. Two of my other patients were subsequently handed over to my friend the late Dr. Latham in 1914, amongst whose cases their records will be found. They are both well and at work to-day. I might have added details of three other advanced cases which have been completely cured, but as they appear elsewhere it is unnecessary to do so. It seems desirable once more to emphasize the fact that Spelling's treatment is of two kinds—namely, (i) serum for acute and subacute cases, (ii) vaccines for early or chronic pulmonary cases, and for all surgical cases. The serum acts rapidly. The symptoms are rapidly diminished and pure and unpurified sera are ready within the first few months. If the serum is stopped before a complete recovery has been established, signs of activity are liable to recur. This is because sera are capable of neutralizing a passive immunity only. It is the vaccines which evoke the active, these act less rapidly than the sera. Improvement under vaccine treatment does not become evident until the organism has had time fully to mobilize its defensive mechanism.

D. W., aged 25, pale youth with typical malar flush. History of anorexia, bad colds. Severe attack of bacemysyphilis which lasted 3 weeks. Troublesome cough, breathlessness. When first seen, in August, 1913, he had cough, expectoration (tubercle bacilli present in sputum), temperature 100, pulse 100; had no night sweats, lost 1 st 6 lb.; there was much dyspnoea, pain in right side, clubbing. Signs of infiltration of left upper lobe and upper half of lower lobe. Sphingiger's vaccine treatment was commenced in August, 1913. In April, 1914, there was no evidence of active disease; temperature, pulse, and weight were normal. Discharged.

Case 3. History of cough, emaciation, lassitude, shortness of breath. When first seen in October, 1913, F. E., thin, anæmic man, aged 35.

the grave risks. For a long time we have been seeing terrible cases of x-ray carcinoma due to excessive x-ray treatment administered ten, fifteen, and twenty years ago.

In ulcerative lupus and in the conditions known as serofuloderma, we find that many local measures rapidly ameliorate the condition. Mild antiseptic treatment, cleansing with peroxide lotion, fomentations, the application of a mild mercurial lotion such as *lotio hydrarg.* flav., etc., and especially an occasional short exposure to x rays, produce a rapid movement. When the ulcers are cleaned up the local application of concentrated actinic light proves of great service. But this type, which often occurs about the muco-cutaneous junction, and is often associated with deep-seated intranasal or glandular disease, may develop with great rapidity and cause much destruction.

It is in this type that my experience shows the importance of combining general with local treatment, and the photographs which I show illustrate this point.

We have had over twenty-three years' experience of the light treatment of lupus at the London Hospital, and to test the permanence of the results following the local application of concentrated arc light by Finsen's method I have, with the aid of my staff, kept myself in touch with most of the patients who have passed through the clinic. In 1908 and again in 1913 I published analyses of these results.<sup>1</sup> This year, however, I made an inspection of the cases classed as cured in 1913 (Class A)—that is, after a lapse of ten years—and although we failed to get in touch with a number of the patients owing to the war, change of address, marriage, etc., we got reliable evidence either from personal examination, medical or other reports, that 132 of the patients had remained cured from ten to twenty-two years, and this in spite of the lack of nutritious food due to war conditions. I append photographs of a characteristic case remaining cured twenty-one years after treatment (Figs. 1, 2, 3).

A second group of cases (Class B) was also examined, and in this type there have been slight relapses, but the majority of the patients have been able to continue in their employment with short intervals for treatment. Some, indeed, have done so well that they would now come into Class A.

With regard to the percentage of cures effected by the local applications of light, our figures tally very closely with those of Professor Reyn, about 70 per cent. This is slightly higher than the Copenhagen figures, but my own observations showed that the type of case seen in the Danish institute was often graver than our own.

#### General Treatment.

We have always had a percentage of intractable cases, the intractability being shown (1) by the fact that the area of lupus increased faster than we could cope with it by the light treatment, and (2) by the extensive involvement of the nasal and sometimes the buccal cavity.

It is in this type of case that we have been looking for some measure which would help to improve the patient's resistance. At first we were very hopeful that the tuberculin treatment, especially after the developments following Sir Almroth Wright's work, would be of great service, and in this we have to record failure except in some ulcerative cases and in cases of serofuloderma, but in many of these apparent cure has been followed by relapse. The dry type of lupus failed to be benefited at all by tuberculin treatment.

Dreyer's defatted antigen is an advance and has appeared to be of distinct value already in the ulcerative type of case. It is too early to predict what will be the result in the cases of dry lupus. In this variety the nodules are so imbedded, very often in connective tissue hypertrophy, that we cannot expect such an active reaction.

In the light bath we have, I am convinced, a most valuable adjunct to the local therapy, and I have now twelve months' experience of this measure in the treatment of the more serious and intractable cases of lupus. Strandberg, working in the Finsen Institute, has shown that intranasal lupus, always an extremely difficult affection

to combat by surgical measures or other local measures, may be cured in the light bath, and I can confirm his observations.<sup>2</sup>

As our installation has been limited and to some extent experimental, we have only dealt with cases which have failed to be cured by the application of light locally, and I am sure Professor Reyn does not overstate the case in claiming that the percentage of cures can be increased from 60 to 90 by a combination of the local application of light with carbon arc-light baths.

At first the sittings are of half an hour's duration, and they are gradually extended until both anterior and posterior surfaces are exposed for two hours. Great care is taken to protect the eyes when the front of the body is exposed. Any open sores are covered by a simple dressing. The sittings are given daily. The group of nude figures round the lamp is surrounded by a screen, and care is taken to prevent the possibility of the blindfolded patient coming too near the arc. We are now treating eight at one arc lamp at once. The effects observed are:

1. Pigmentation of whole surface.
2. Rapid healing, especially of moist, rather fungating lesions.
3. Increase of body weight.
4. Improvement in the general condition.
5. Usually an increase of the small lymphocytes in the blood count.

The boy whose photographs are shown (Figs. 4, 5, 6) came under treatment in September, 1921. He was treated by the local application of concentrated light until May, 1922, and although parts of the affected area healed under this measure the disease spread at the periphery. He was then submitted to the light bath only, local treatment being suspended, and in the third photo the improvement is obvious. We have since combined both therapeutic measures and have cleared the few remaining nodules.

The girl whose photographs are appended (Figs. 7, 8, 9, 10) had steadily increasing lupus of the face, neck, and upper limbs, in spite of vigorous local treatment. In six months every lesion had soundly healed with the combination of light baths administered daily and local treatment. Her general physique has also improved remarkably.

The young man whose case was also illustrated had been under local treatment for a year with very poor result. He was a lazy, untidy youth from an agricultural district, and I had even advised his return home as incurable, when the light bath was introduced. He was one of the first patients and we were gratified to find that he responded at once. All his lesions healed, including an old sinus over the right scapula, and his general condition, mental and physical, improved so much that he has returned to his home and has at once obtained a better post.

I should like to draw special attention to the general improvement in the condition of patients under the light bath. There is a feeling of well-being, the patients become brighter and more active, the skin generally becomes clearer, and they put on weight. Examinations of the blood show that there is in many cases a marked increase in the small lymphocytes. The listless, apathetic lad or girl begins very shortly to take an interest in his or her appearance, and there is an alertness about these patients which has greatly impressed both the medical and nursing staffs attached to my clinic.

At first we had to start in a very humble way with one 25-ampère lamp, but we were soon convinced of the value of the light bath and a 50-ampère lamp was installed. We have had 32 cases under treatment, and hope to increase our installation at an early date.

The cases described show the remarkable efficacy of the general treatment, but we have also observed that the light bath treatment intensifies the effect of the local action of concentrated light on the lupus lesions and materially shortens the time required for effecting a cure. We find we can get our patients well bronzed in about a fortnight. In some cases, particularly in girls, there is a rather acute light dermatitis with vesication and free desquamation, but this is of no moment.

EYELID PENETRATED IN SEPARATE PLACES

the white vertical streaks an eighth of an inch apart; on reversing the lid, these were seen to run backwards towards the joints substantially, where one of them remained in the three tip of an eyelash. F. The second one, although it had penetrated the lid, had not perforated the conjunctiva, and was left for the time, as it was causing no irritation. As it was impossible to see the proximal end of either lash the former was removed by cilia forceps from its free end. It came away complete and with no trouble. Apparently both lashes had grown backwards from their roots, through the substance of the lid.

London. W.

SPYDEX TIBULES, L.R.C.S. and P.D.M.

Two severe cases of pulmonary tuberculosis whose records are available. One improved with partial serum treatment, the other died after a few injections, his case being probably too far advanced to respond to the very partial treatment available.

Cases 19 and 20.

Cases 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, 100, 101, 102, 103, 104, 105, 106, 107, 108, 109, 110, 111, 112, 113, 114, 115, 116, 117, 118, 119, 120, 121, 122, 123, 124, 125, 126, 127, 128, 129, 130, 131, 132, 133, 134, 135, 136, 137, 138, 139, 140, 141, 142, 143, 144, 145, 146, 147, 148, 149, 150, 151, 152, 153, 154, 155, 156, 157, 158, 159, 160, 161, 162, 163, 164, 165, 166, 167, 168, 169, 170, 171, 172, 173, 174, 175, 176, 177, 178, 179, 180, 181, 182, 183, 184, 185, 186, 187, 188, 189, 190, 191, 192, 193, 194, 195, 196, 197, 198, 199, 200, 201, 202, 203, 204, 205, 206, 207, 208, 209, 210, 211, 212, 213, 214, 215, 216, 217, 218, 219, 220, 221, 222, 223, 224, 225, 226, 227, 228, 229, 230, 231, 232, 233, 234, 235, 236, 237, 238, 239, 240, 241, 242, 243, 244, 245, 246, 247, 248, 249, 250, 251, 252, 253, 254, 255, 256, 257, 258, 259, 260, 261, 262, 263, 264, 265, 266, 267, 268, 269, 270, 271, 272, 273, 274, 275, 276, 277, 278, 279, 280, 281, 282, 283, 284, 285, 286, 287, 288, 289, 290, 291, 292, 293, 294, 295, 296, 297, 298, 299, 300, 301, 302, 303, 304, 305, 306, 307, 308, 309, 310, 311, 312, 313, 314, 315, 316, 317, 318, 319, 320, 321, 322, 323, 324, 325, 326, 327, 328, 329, 330, 331, 332, 333, 334, 335, 336, 337, 338, 339, 340, 341, 342, 343, 344, 345, 346, 347, 348, 349, 350, 351, 352, 353, 354, 355, 356, 357, 358, 359, 360, 361, 362, 363, 364, 365, 366, 367, 368, 369, 370, 371, 372, 373, 374, 375, 376, 377, 378, 379, 380, 381, 382, 383, 384, 385, 386, 387, 388, 389, 390, 391, 392, 393, 394, 395, 396, 397, 398, 399, 400, 401, 402, 403, 404, 405, 406, 407, 408, 409, 410, 411, 412, 413, 414, 415, 416, 417, 418, 419, 420, 421, 422, 423, 424, 425, 426, 427, 428, 429, 430, 431, 432, 433, 434, 435, 436, 437, 438, 439, 440, 441, 442, 443, 444, 445, 446, 447, 448, 449, 450, 451, 452, 453, 454, 455, 456, 457, 458, 459, 460, 461, 462, 463, 464, 465, 466, 467, 468, 469, 470, 471, 472, 473, 474, 475, 476, 477, 478, 479, 480, 481, 482, 483, 484, 485, 486, 487, 488, 489, 490, 491, 492, 493, 494, 495, 496, 497, 498, 499, 500, 501, 502, 503, 504, 505, 506, 507, 508, 509, 510, 511, 512, 513, 514, 515, 516, 517, 518, 519, 520, 521, 522, 523, 524, 525, 526, 527, 528, 529, 530, 531, 532, 533, 534, 535, 536, 537, 538, 539, 540, 541, 542, 543, 544, 545, 546, 547, 548, 549, 550, 551, 552, 553, 554, 555, 556, 557, 558, 559, 560, 561, 562, 563, 564, 565, 566, 567, 568, 569, 570, 571, 572, 573, 574, 575, 576, 577, 578, 579, 580, 581, 582, 583, 584, 585, 586, 587, 588, 589, 590, 591, 592, 593, 594, 595, 596, 597, 598, 599, 600, 601, 602, 603, 604, 605, 606, 607, 608, 609, 610, 611, 612, 613, 614, 615, 616, 617, 618, 619, 620, 621, 622, 623, 624, 625, 626, 627, 628, 629, 630, 631, 632, 633, 634, 635, 636, 637, 638, 639, 640, 641, 642, 643, 644, 645, 646, 647, 648, 649, 650, 651, 652, 653, 654, 655, 656, 657, 658, 659, 660, 661, 662, 663, 664, 665, 666, 667, 668, 669, 670, 671, 672, 673, 674, 675, 676, 677, 678, 679, 680, 681, 682, 683, 684, 685, 686, 687, 688, 689, 690, 691, 692, 693, 694, 695, 696, 697, 698, 699, 700, 701, 702, 703, 704, 705, 706, 707, 708, 709, 710, 711, 712, 713, 714, 715, 716, 717, 718, 719, 720, 721, 722, 723, 724, 725, 726, 727, 728, 729, 730, 731, 732, 733, 734, 735, 736, 737, 738, 739, 740, 741, 742, 743, 744, 745, 746, 747, 748, 749, 750, 751, 752, 753, 754, 755, 756, 757, 758, 759, 760, 761, 762, 763, 764, 765, 766, 767, 768, 769, 770, 771, 772, 773, 774, 775, 776, 777, 778, 779, 780, 781, 782, 783, 784, 785, 786, 787, 788, 789, 790, 791, 792, 793, 794, 795, 796, 797, 798, 799, 800, 801, 802, 803, 804, 805, 806, 807, 808, 809, 810, 811, 812, 813, 814, 815, 816, 817, 818, 819, 820, 821, 822, 823, 824, 825, 826, 827, 828, 829, 830, 831, 832, 833, 834, 835, 836, 837, 838, 839, 840, 841, 842, 84

he was unable to swallow anything. The carbon arc lamps gave no relief at first, but at the end of six weeks' persistent treatment the larynx was practically painless and the use of all local anaesthetics and hypnotics had been omitted. There was no fever during the treatment, and the patient improved generally, but Dr. Johnston could detect no change in the pulmonary physical signs. The patient left the sanatorium about three months ago and up to the present there had been no return of the pain and his general condition as well as the pulmonary and laryngeal lesions had improved steadily. Dr. Johnston had also used the carbon arc lamps in a few cases for the treatment of tuberculous sinuses which were not healing under other methods of treatment. He referred especially to the case of a young man who was riddled with tuberculous foci—four large sinuses over four ribs on the right side in front, two sinuses connected with the glands in the right axilla, one on the right side of the neck, one on the left thigh, both from glands, an abscess over the right sacro-iliac joint, and a number of sinuses, both dorsal and plantar, on the left foot. The patient had also a mild lesion of the right upper lobe and was greatly emaciated and constantly febrile, and the prognosis looked very grave. He has been treated with the arc lamps for the last four months with remarkable results, for all the foci had healed except the foot, which, however, had much improved; his general condition was excellent and he was afebrile. This patient had been treated by various methods in several institutions for a long time without any improvement; and he had been at Tor-na-Dee for a considerable time prior to the commencement of the arc lamp treatment and was not doing well. Dr. Johnston felt certain that his present state was due to this method of treatment. His experience was very limited as yet, but he could not help feeling that there was a very definite sphere of usefulness for this method of treatment in a proportion of cases of tuberculosis. In painful tuberculous laryngitis he did not think that heliotherapy would give as good results as the arc lamps, especially if the lungs were gravely involved. In this country, where sunshine was somewhat fickle, especially in winter, it was easily conceivable that, in a proportion of patients suffering from so-called surgical tuberculosis, regularly applied treatment by the carbon arc lamps might give better results than irregularly applied heliotherapy.

## DISCUSSION ON THE PRESENT POSITION OF THE SURGICAL TREATMENT OF PULMONARY TUBERCULOSIS.

### OPENING PAPER

BY

J. GRAVESEN, M.D. COPENHAGEN,

Medical Superintendent, Vejlebjerg Sanatorium, Denmark.

#### Introduction.

The particular kind of surgical treatment which has so developed as to become a lasting adjuvant to the present aid against unilateral, or chiefly unilateral, cases of pulmonary tuberculosis is based upon the experiences gained by the work with artificial pneumothorax. The principles of this method have put an end to all previous devices (incision with drainage of cavities, excision of lung lobes, etc.), which, therefore, need not be mentioned.

The immense amount of work that has been done on pneumothorax treatment, its principles and technique, is evidence of its value. Its value, however, is not to be judged merely from the point of view of the results of cure recorded by the many different authors all over the world. The results may often seem rather doubtful, or at least somewhat modest. But it has to be remembered that, besides the mere results, artificial pneumothorax has brought about a considerable progress in our knowledge with regard to many questions the importance of which had not hitherto been sufficiently realized. Light has been thrown upon many anatomical, physiological, biological, diagnostic, and therapeutic problems through the experience derived

from the method of measuring the endopleural pressure, from the use of x rays, and from many other additional means developed along with artificial pneumothorax.

When considering the results of cure by this treatment it should be borne in mind that artificial pneumothorax and subsequent methods are being used only in those advanced cases (third stage) which have a very poor prospect by the ordinary régime, even with the addition of specific remedies. This fact, of course, must be remembered before any attitude is taken towards the question under discussion. Moreover, it should be realized that artificial pneumothorax, as well as collapse operations, depend to a very great extent upon a very scrupulous technique and a thorough familiarity with all the indications and complications. Undoubtedly this fact explains many of the very different opinions published by various authorities on the methods in question.

Above all, the results of artificial pneumothorax have to be judged according to the anatomical and physiological possibility of deriving full benefit from the treatment. In order to settle the actual results and to justify further—and more risky—methods in cases where the induction of pneumothorax is technically impossible, and therefore unsuccessful, it is necessary to classify the cases with regard to the influence exerted by the presence of pleural adhesions.

Such classification has been utilized in the largest series of cases yet published on this subject—namely, that of Saugman<sup>1</sup> (Vejlebjerg Sanatorium, Denmark). A comprehensive view of these 211 third-stage cases (two to twelve years after discharge) shows a lasting positive result of the pneumothorax in 38 per cent. of all cases in which a pneumothorax of any noteworthy extent could be established. A comparison of this figure with the percentage of cure, 11 per cent., in cases in which pneumothorax had to be given up owing to more or less universal adhesions, gives a fair credit to artificial pneumothorax.

The further classification of the former group explains why the results are not still better. The injurious influence of adhesions even in some of the cases in which pneumothorax is practicable is apparent from the following tables showing the condition of the patients three to thirteen years after discharge.

| GROUP I.—Cases with Complete Pneumothorax without Adhesions. |     |     |                     |
|--------------------------------------------------------------|-----|-----|---------------------|
| Able to work                                                 | ... | ... | 33 = 70.2 per cent. |
| Not able to work                                             | ... | ... | 1 = 2.1 " "         |
| Died from tuberculosis                                       | ... | ... | 11 = 23.4 " "       |
| Died from other causes                                       | ... | ... | 1 = 2.1 " "         |
| Unknown                                                      | ... | ... | 1 = 2.1 " "         |
| 47                                                           |     |     |                     |

| GROUP II.—Cases with Complete Pneumothorax but with Localized Extended Adhesions. |     |     |                    |
|-----------------------------------------------------------------------------------|-----|-----|--------------------|
| Able to work                                                                      | ... | ... | 14 = 33½ per cent. |
| Died from tuberculosis                                                            | ... | ... | 28 = 66½ " "       |
| 42                                                                                |     |     |                    |

| GROUP IIIA.—Cases with Incomplete Pneumothorax but with Larger Adhesions. |     |     |                    |
|---------------------------------------------------------------------------|-----|-----|--------------------|
| Able to work                                                              | ... | ... | 5 = 11.1 per cent. |
| Died from tuberculosis                                                    | ... | ... | 39 = 86.7 " "      |
| Died from other causes                                                    | ... | ... | 1 = 2.2 " "        |
| 45                                                                        |     |     |                    |

| GROUP IIIB.—Cases with Universal Adhesions—no Pneumothorax Practicable. |     |     |                    |
|-------------------------------------------------------------------------|-----|-----|--------------------|
| Able to work                                                            | ... | ... | 9 = 11.8 per cent. |
| Not able to work                                                        | ... | ... | 3 = 3.9 " "        |
| Died from tuberculosis                                                  | ... | ... | 63 = 81.8 " "      |
| Unknown                                                                 | ... | ... | 2 = 2.6 " "        |
| 77                                                                      |     |     |                    |

These tables\* clearly show how frequently the adhesions handicap the full benefit of artificial pneumothorax and what excellent results that treatment would be able to give if the injurious influences of the adhesions could be removed. It is no wonder, therefore, that somewhat extreme attempts have been made in cases of adhesions to provide for the diseased lung such conditions of lung collapse as are present in an adhesion-free pneumothorax. I cannot mention here all of the numerous suggestions made by different authors towards this end, as a good many of the suggestions have

\* The statistics in these tables are worked out on cases treated before any additional operation had been undertaken.

# Reviews.

## HYGIENE OF THE WAR.

Two volumes on *Hygiene of the War*, forming part of the official *History of the Great War*, have been published. The first volume deals with sanitary organization, instruction in hygiene, purification and supply of water, the disposal of waste products, the housing and clothing of the soldier, and the hygiene of transports; the second with various matters relating to food, and with special diseases and dis-

producing insects.

The general success of the military sanitary adminis-

tration, especially in France, is well recognized, but Sir William Macdonald, the editor of the series, states in his preface to these two volumes that it has been difficult to measure the saving of man power. He takes the morbidity rates for the chief water-borne diseases in the South African war as the basis for comparison, and states that in that war 58,000 out of an average strength of 200,000 suffered from typhoid and over 8,000 died, while on the Western Front in the late war less than 7,500 were affected in an average strength of a million and a quarter, and there were only 266 deaths.

Similarly, the admission rate for dysentery, which was 6.18 in any year on the Western Front. In dealing with water supplies the editor refers also to the value of the water reconstructions of an expert geologist in Egypt and Palestine. Among the new types of work was the whole sale disinfection of persons and clothing, the need for which was increased by the demonstration in 1918 that the house-

was the conveyor of trench fever.

It was shown that the long accepted figure of 0.3 per cent. of the strength as the daily admission to hospital was seldom exceeded when sanitary measures were effectively carried out, and it became a valuable mark above which investigation would always show some obvious defect in sanitary control.

The early efficiency of the sanitary organization was due to the fact that the pre-war scheme formed a sound foundation on which extensions and new methods could be based. It is laid down that every commander is responsible for the health of his men and the sanitation of the area which he occupies, and that he should have an expert sanitary officer as his adviser. In order to give satisfactory sanitary advice and supervision in detail divisional sanitary sections were organized, but owing to the frequency with which divisions were moved, it was subsequently decided that more effective sanitary control could be exercised by having sanitary units for fixed areas and giving them control of laundries and baths. The rapid increase in sanitary personnel was brought about mainly through the London Sanitary Companies of the Territorial Force which acted as training centres. Over 1,000 beds per 1,000 troops proved sufficient for the usually notifiable diseases, but also of scabies, trench fever, influenza, venereal disease, and other diseases in which special investigation was being carried out, was provided for.

The account given of the supply of safe drinking water constitutes a detailed and instructive dissertation on the methods by which water was obtained, purified and conveyed to the soldier in no matter what position he might be. In the investigation was being carried out, was provided for.

Opportunities were afforded for laboratory work of various kinds, including the provision of mobile bacteriological laboratories to assist in the early diagnosis of infectious diseases, and also of motor vans fitted as hygiene laboratories. Early notification, not only of the usually notifiable diseases, but also of scabies, trench fever, influenza, venereal disease, and other diseases in which special investigation was being carried out, was provided for.

the bleeding spot or high endopleural pressure, established by injection of saline solution into the pneumothorax). One of the reasons why we have not observed any bleeding is probably because we always use a weak, redly glowing galvano-cautery. This precaution makes the operation somewhat longer, but at the same time safer.

In six of our cases a serious empyema developed after the operation; the cause of this complication was almost always to be found in the attempt to cauterize rather extensive adhesions. Simple exudates were observed after the operation in six cases, but had no injurious influence.

It seems evident to us, and also from the experiences published by other authors (up to date Jacobaeus himself has used his method in not less than 90 cases), that none of the technical or clinical complications is of such grave importance as to warrant abandoning the method in suitable cases. But it is also true that the operation demands a good deal of practice in handling the instruments and in judging the different conditions which may be found. The common criticism of the method—referring to the difficulties of the technique—is, however, in our opinion to be explained by lack of proper practice. Another criticism of the method is the comparatively narrow field of indication; but, as a matter of fact, this circumstance should not be allowed to condemn the method in really suitable cases.

Our work on these lines has obtained the following results:

Out of a still larger number of cases, in which thoracoscopy has been used, cauterization was performed or tried in 35 cases. Cauterization was technically successful (that is, sufficient for a complete collapse of the lung) in 22 cases; 17 of these derived a lasting clinical benefit from the operation (disappearance of bacilli and symptoms). In 13 cases the operation was given up after an incomplete cauterization; some of these cases, too, showed improvement after the operation.

Although we feel justified by these results in recommending the method, we are still confronted by a class of cases belonging to this group which are not suitable for the application of the method. In such cases we usually try for a longer period the most energetic pneumothorax technique that is practicable, and often we acquiesce in a less complete collapse, obtaining only relative results. If, however, further observation shows that the prospect of lasting improvement in such a case actually depends upon further surgical treatment we consider the methods mentioned under the next heading.

In two cases we have tried to provide the complete lung collapse by means of a pleurotomy with manual or instrumental loosening of such extended adhesions as could not be cauterized. But in both cases such serious complications (post-operative haemorrhage and open empyema) occurred, as to necessitate our abandoning these operations. The same experiences are published by several other authors with regard to pleurotomy.

### III. Artificial Pneumothorax not Possible to any Satisfactory Degree: Thoracoplasty.

Although it may be true that for Jacobaeus's method there is left only a narrow field of real usefulness, a glance at Groups IIIa and IIIb of the above tables (p. 506) reveals a large number of cases entirely lacking the lasting benefit of artificial pneumothorax. It will be easily understood that a clinical observation of the facts expressed by such statistics has prompted our efforts to introduce in our treatment such operations as had been worked out as substitutes for artificial pneumothorax. As our work with the thoracoplastic operations has preceded we have experienced to a fair extent the advantages as well as the drawbacks involved in these methods. The sum of our experience is, however, in absolute favour of thoracoplasty, provided the operation is used in well selected cases and every attention is paid to the physiological and technical demands.

It has been our aim to select the most useful modifications published by different authors, especially on the Continent and in our brother countries in Scandinavia, and thus to work out a technique which combines the advantages of the different methods. As a whole we have followed Sauerbruch's<sup>2</sup> technique, which embraces the largest fund of theoretical and practical experiments published on this subject. But also Brauer,<sup>3</sup> who was the pioneer in solving the problems of a successful thoracoplastic operation, has a

great share in the line of work adopted by us. Of the Scandinavian authors we are obliged to mention P. Bull,<sup>4</sup> and Jacobaeus and Key,<sup>5</sup> whose recent publications are of great value to the discussion.

Since 1916 we have treated 110 patients with thoracoplasty: 105 of these were operated upon for pulmonary tuberculosis, 3 for old tuberculous empyema with external fistulae, and 2 for bronchiectasis. Previous to the 105 cases of pulmonary tuberculosis on which our experience in this connexion is based, we had experimented with the earlier methods of thoracoplasty (Brauer, Friedrich) carried out by surgical colleagues in other hospitals. The results of four such cases, however, hardly justified further experiments on the same lines; in all the cases but one the effect failed, and in the one positive case the condition of the lung and heart functions was considerably impaired. For several years, therefore, no thoracoplastic operation was performed on our patients. When the further development of the technique had provided a better prospect, the method was again taken up for renewed study, and in contrast to the previous attempts we were now enabled, by the installation of a full surgical outfit at our own sanatorium, to carry out the operation ourselves without any discontinuation of the ordinary sanatorium treatment of our patients. We emphasize this advantage as a very important one for obtaining the best possible results.

The indication for thoracoplasty arises when, in cases fit for lung collapse treatment, the careful attempts of artificial pneumothorax have actually failed. Before entering upon this alternative operation, however, we always revise the indication very carefully, as we believe a considerable restriction to be necessary when proceeding from the question of artificial pneumothorax to that of thoracoplasty. On account of the greater risk and the irreparable conditions involved in thoracoplasty, a more pressing need of collapse of the diseased lung and a more reliable condition of the better lung are demanded than in regard to artificial pneumothorax alone. Nevertheless, the striking examples of good results, even when the better lung has been considerably affected, have had the result that occasionally we have felt justified in giving such patients as might gain a little and could lose nothing a chance by the operation. It cannot, however, be denied that this indication as a whole acts unfavourably upon our statistical results. The general condition of the patient and the complication with other localizations of tuberculosis or other diseases also seem to us to claim more deliberation than with regard to artificial pneumothorax lest thoracoplasty should get a bad reputation.

Having settled the indication for a particular patient we come to the next question to be solved—namely, the working out of the plan of operation to be followed in this individual case. It is a common statement, with which we cordially agree, that the chief problem regarding plastic operation is to individualize the operation according to the peculiarities of the single case. The deliberations in this respect are particularly concerned with two questions: (1) Should a partial or a complete thoracoplasty be done? (2) Should the operation be performed in one, two, or more stages?

(1) A partial thoracoplasty may be considered sufficient either when the affection (for instance, a cavity) is localized to a limited area of the lung or when a partial pneumothorax has been so established as to provide collapse for the upper or, more frequently, the lower part of the lung.

In a few cases where the disease was well localized to a certain lobe we were able to secure a full effect by an operation which left some of the ribs intact. In three cases of large basal cavities the upper two or three ribs were not resected, and the result of these operations proved very satisfactory. In the more frequent cases of apical cavities, however, we do not consider it safe to let the lower part of the lung remain expanded, as a post-operative aspiration of sputum into the moving lower lobe is likely to produce pneumonia or a secondary tuberculous affection.

If only the lower lobe is immobilized by a partial, basal pneumothorax it may be advisable to abstain from complete thoracoplasty by leaving the lower ribs intact. This combination of a partial pneumothorax and a partial thoracoplasty formed the plan of operation in three of our cases.

THE ACTION OF RADIUM.

The Jacksonian Essay on *The Effects of Radium upon Living Tissues*, by Dr. Sidney Fox, has together with a paper on the treatment of haemorrhage by radium, been published as a separate volume. The author describes a series of experiments in which the ovary of the cat was exposed to the action of varying doses of rays for periods ranging from half an hour to twenty-four hours. The animals were allowed to survive for from thirty-six hours to twelve weeks. The general conclusions are that with strong doses of radiation, where the radium is brought into direct contact with the tissue, the effects are produced in a few hours. With moderate doses there is a definite latent period before any change is noted, but though delayed the microscopical changes are identical. The author states that apart from the engorgement of vessels and haemorrhages, the first noticeable effect is upon the nuclei of the primary follicles; fragmentation of the nucleus occurs, but the cytoplasm only shows changes later; he concludes that the cell is probably killed by action upon the nucleus. Radium rays, he states, show differential action upon vital cells; endothelium of vessels, ovarian follicles, lymphatic tissues, and white blood cells are rapidly destroyed, whereas nervous, fibrous, and cartilaginous cells are more resistant. This differential action is most marked in rapidly dividing and embryonic tissues. The author has treated fifty cases of carcinoma of the uterus, vagina, and cervix with radium. He concludes that the younger the patient the worse is the outlook, and that the best results are obtained from patients at, or following, the menopause. The prognosis in the endocervical type of carcinoma is grave, as it is rarely diagnosed in the early stage. Of squamous carcinoma, the fungating type respond to treatment better than the ulcerative. Three of the cases were treated in the early stage of the disease; two of these were alive and well eighteen months after treatment and there was no sign of recurrence. The remaining forty-seven cases were inoperable. Four of these were clinically free from disease six to twelve months after treatment; eight remained unrelieved; three received marked benefit from cessation of haemorrhage, relief of pain, and modified discharge.

The success of the book on cystoscopy and ureteral catheterization, by Drs. G. Laroche and J. Heitz-Boyer, has induced the authors and publishers to produce a second edition. Several noteworthy changes have been made. In the first place the work is issued as a single volume, and a certain amount of space has been saved by insisting less on the distinction between cystoscopy with instruments giving a reversed image and cystoscopy with the equal facility. Moreover, the chapter on the optics of cystoscopes and the interpretation of images has been entirely remodelled, and this somewhat dry subject has certainly benefited by the rewriting. An excellent chapter is that which deals with the cystoscopy of patients suffering from enlargement of the prostate. The authors have long been recognized authorities on the cystoscopic appearance of enlargement, and their description of the vesical aspect of an enlarged prostate is excellent. Great emphasis is laid on the importance of ascertaining the relation of the vesical neck to the ureteral orifices. As the authors point out, in a normal bladder it is impossible to view simultaneously in the same field the bladder neck and the orifices. When hypertrophy exists, even when it is still slight, it is possible to see bladder it is impossible to view simultaneously in the same field the bladder neck and the orifices. When hypertrophy exists, even when it is still slight, it is possible to see

The art of pyelography has also advanced since the appearance of the first edition in 1914. Various pyelograms are included in the new work. The examples of normal renal pelvises are excellent, but in selecting an illustration of hydronephrosis it would have been better to have chosen a less advanced case. An advanced case of hydronephrosis can be diagnosed apart from pyelography, and it is in the detection of the earliest changes in the pelvis and calyces that pyelography is of such service. The authors have not emphasized this point sufficiently, nor dwelt enough on the interpretation of pyelograms that show an early stage of dilatation. Surely it is only by a better knowledge of the beginning of hydronephrosis that progress will be made and that kidneys otherwise condemned to destruction will be saved. The first edition of this work is sufficiently well known to make it unnecessary to write at greater length on the merits of the second. A perusal of its pages should be sufficient to convince the most sceptical of the importance of modern urological methods in the diagnosis and treatment of lesions of the genito-urinary tract.

CONGENITAL HIP DISLOCATION.

In *La luxation congénitale de la hanche*, Dr. P. Le Danyan of Rennes attempts to solve the long discussed problem of the etiology of congenital dislocation of the hip. The causes of this deformity and its sexual distribution have up to the present time defied investigation. According to Dr. P. Le Danyan the causes are the cerebral development of man, and the consequent increase in size of cranium, which by necessitating a more capacious pelvis has caused disadvantageous changes in the position and form of the acetabulum. He quotes statistics to show that the dislocation is more frequent in males than in females. The authors have long been recognized authorities on the cystoscopic appearance of enlargement, and their description of the vesical aspect of an enlarged prostate is excellent. Great emphasis is laid on the importance of ascertaining the relation of the vesical neck to the ureteral orifices. As the authors point out, in a normal bladder it is impossible to view simultaneously in the same field the bladder neck and the orifices. When hypertrophy exists, even when it is still slight, it is possible to see

*The Effects of Radium upon Living Tissues*, with Special Reference to its use in the Treatment of Malignant Tumours, by Dr. Sidney Fox, London: H. K. Lewis and Co. Ltd. 1922. (Penny 8vo, pp. 127, 32 figures, including 9 plates, 5s. net.)

*Traité pratique de cystoscopie et de cathétérisme urétral*, par G. Laroche et J. Heitz-Boyer, Douzième édition, entièrement remaniée. Paris: Masson et Cie, 1923. (Roy. 8vo, pp. 450; 214 figures, 43 plates, Fr. 100.)

*La luxation congénitale de la hanche*, par Dr. P. Le Danyan, Rennes: Édition des communications médicales dirigées par le Dr. Alfred Fournier, 1923. (Cr. 8vo, pp. 256; 113 figures, Fr. 15.)

Professor Chr. Saugman. According to the original plan Saugman himself should have enjoyed this opportunity of giving an account of the studies here presented, in the development of which he has been the great master. His death in February of this year has thwarted this plan, to which he had been looking forward with much delight. His enormous energy, his profound knowledge, his clinical capacity, and his unique personality will be missed on this occasion, as it is missed in all the spheres of his great life work.

## DISCUSSION.

Mr. J. E. H. ROBERTS (London) said it was not necessarily true that bad results were due to adhesions, but infection was more virulent in cases where adhesions were strongest. He had lately modified his views regarding the Jacobaeus operation for cauterizing adhesions. He believed that in many cases it was a good procedure, but in others the adhesions were so firm that thoracoplasty had to be performed. He urged the importance of careful preparation of a case to be subjected to thoracoplasty. He preferred not to rely on a local anaesthetic; gas and oxygen was the anaesthetic of choice. The after-treatment was as important a factor as the operation itself. The chest wall should be immobilized by strapping for at least ten days, and physical exercises should be practised.

Dr. VERE PEARSON (Mundesley Sanatorium, Norfolk), in discussing the choice of patient for artificial pneumothorax, urged that a fair trial of sanatorium treatment should first be given. He thought it unwise to refuse to operate because there was a possibility of adhesions being present. He maintained that the ordinary physical signs were more important than x-ray evidence. If a case was deemed suitable for thoracoplasty this operation should not be delayed too long.

Dr. L. S. T. BURRELL (London) said that one great principle in the treatment of tuberculosis was rest of the diseased part, and the best way to rest a diseased lung was to induce an artificial pneumothorax. He thought that this treatment should be given more often and in an earlier stage of the disease than was usually the case at present. When treating a patient by artificial pneumothorax he kept him in bed at absolute rest until the temperature had been normal for at least a month, and then allowed him to begin to get up and do a little more each day until he was fit to be up all day. He was then able to begin training, and a sanatorium was the best place for him; he should stay there until all symptoms had gone and he was able to lead a normal life without fatigue. Then if necessary he returned to work, the pneumothorax being kept up for two or three years, when the lung might be allowed to re-expand gradually. The principle of this treatment was rest of the body and of the diseased part, followed by training of the body but rest of the diseased part. The importance of rest could not be too strongly emphasized. When a patient contracted consumption he was in for a big fight, and the result depended very largely upon himself. The wise man would avoid all exertion and lead the quietest of lives for at least two years.

It followed that if both lungs were involved this treatment must be modified, and this was one reason why he advocated its early adoption. It might be said that the unilateral cases were just the ones that tended to recover with or even without any treatment, but it must not be forgotten that every case started as a unilateral one. The question was, did pneumothorax tend to prevent the spread of the disease? He suggested that it undoubtedly did so. Of his first 150 cases 45 had disease in one lung only, and of these 32 had lost their tubercle bacilli and symptoms for at least the last six months, 9 were much better, and 2 were dead. In 26 cases the other lung was affected, though less

than one-third of it, and of these only 6 had lost the tubercle bacilli and symptoms for at least the last six months, and 8 were dead. What, one asked oneself, would have been the result if these 26 had had a pneumothorax earlier? Another reason for inducing a pneumothorax in earlier cases was that one was less likely to find adhesions or adherent pleura, and although these might be dealt with by one of the methods described by Dr. Gravesen, the position of the patient was much more grave. Thoracoplasty meant the permanent collapse of one lung; it was accompanied by a good deal of shock, and there was a considerable mortality. What was the risk in artificial pneumothorax? He had treated 224 patients by this means and had put a needle into the pleural cavity over 4,300 times, with one fatality. He therefore agreed with Dr. Gravesen that artificial pneumothorax should be tried first; failing this it might be possible to divide the adhesions, and he thought the method described by Professor Jacobaeus was the best, although, in his own experience, very few cases were suitable. Thoracoscopy, however, was often of great value in diagnosis, and was free from pain or danger. Division of adhesions by operation was, in his opinion, distinctly dangerous. Let them not use the word "cure." He had spoken strongly in favour of treatment by artificial pneumothorax, but of the consumptives who had come to his outpatient department during the last five years he had advised pneumothorax treatment in only 15 per cent. In other words, he had recommended other treatment in 55 out of every 100 cases. However, the more he saw of the disease the more convinced he was that the value of pneumothorax treatment was not recognized, and should be more often used. It was not a cure, but it might be said that it was a very great advance in treatment. When a so-called cure came before the public they knew what it meant—many pitiful letters and painful interviews—and it was their sad duty to say that there was no cure. Lastly, he asserted that success in treatment depended on strict attention to detail. After a few months' practice anyone could induce an artificial pneumothorax and give the refill, but only experience could tell how much gas to give and when to give it, how much exercise to allow and how much rest. Each patient must be treated as an individual, and given individual treatment.

Mr. A. TUDOR EDWARDS (London) said that he proposed to pay attention to two methods only for the surgical treatment of pulmonary tuberculosis. The direct treatment of pulmonary tuberculosis—namely, drainage of the cavity—was adopted only to be rapidly abandoned, as the abscesses continued to discharge through the bronchus with the super-added complication of a bronchial fistula on the chest wall. Successful attempts had been made in rare instances with a view to total extirpation of the infected focus, but their scope was limited and their technical difficulty and the resulting shock were prohibitive. The general acceptance of the beneficial effects of artificial pneumothorax had considerably influenced the position of surgery with regard to pulmonary tuberculosis. The tendency of surgery was to amplify or replace artificial pneumothorax, where owing to mechanical factors the collapse was either incomplete as a result of band-like adhesions, or impossible from the presence of generalized surface adhesions.

Where band-like adhesions were present these could be divided with the cautery under vision through the thoracoscope. This instrument was introduced through an intercostal space under local anaesthesia, and the interpleural space examined. The appearance of the bands was quite characteristic. [Mr. Tudor Edwards showed some coloured drawings of different portions of the pleural cavity, which were made from actual cases in the Brompton Hospital, and for the reproduction of which he acknowledged his indebtedness to his friend and colleague Dr. Bennett.] The actual operation was performed by the introduction of a narrow electric cautery through another convenient interspace, and the band divided under vision. It would be found that the number of bands present was considerably in excess of those actually shown by x rays, but those others that were seen did not offer much difficulty in division, as they were finer and

certain indication for cauterization; but it was a narrow one. Where adhesions were multiple the pleura might be opened in order to separate them, but he thought this was inadvisable, and where the lung was closely adherent intrapleural separation was, he was sure, quite wrong. Under these conditions pneumolysis might be done, but the difficulty of the packing material became a serious consideration. He was much interested in Dr. Gravesen's trial of packing the gauze and allowing the space to granulate up, as that was quite new to him.

With regard to thoracoplasty, Dr. Riviere thought that there was no doubt that this was the operation *par excellence* in well selected cases of one-sided disease with adhesions preventing pneumothorax. The operations he had had done were performed under gas and oxygen, and no undesirable results appeared to follow the use of that anaesthetic. It was interesting to hear from Dr. Gravesen that he was now supplementing his local anaesthesia with ether given at a late stage of the operation. Looking through the records of thoracoplasty as done by French surgeons, mostly at Dumarest's instigation, he was struck by the fact that most of the cases needed a general anaesthetic before the end of the operation was reached. Surely if this was now admitted by so experienced an institution as the Vejlebjerg Sanatorium, it would be better, and on the whole safer, if a general anaesthetic was given at the beginning and carried right through. It would be interesting to have Dr. Gravesen's views as to the dangers or disadvantages of this, and also whether he had used gas and oxygen, now much favoured in this country, as the safest anaesthetic to give in this class of case. They were all greatly indebted to Dr. Gravesen for having filled the place at the Annual Meeting of that great colleague of his whose presence would be missed by many all the world over.

### DISCUSSION ON

### THE SOCIAL ASPECTS OF TUBERCULOSIS,

WITH SPECIAL REFERENCE TO ITS INFECTIVITY.

#### OPENING PAPER

BY

JANE WALKER, M.D.,

East Anglian Sanatorium, Nayland, Colchester.

WHEN the Section of Tuberculosis did me the honour of asking me to open the discussion on this subject, I accepted their invitation with full knowledge of the difficulty of my task, and of the certainty that I laid myself open to severe, if not destructive, criticism. It is impossible to overestimate the importance of the subject. Tuberculosis is rightly regarded as one of the great killing diseases, being responsible for 10 per cent. of all deaths. It is the penalty we pay for our civilization, such as it is—in a perfect civilization it should be absent. It is a many-sided disease, being concerned with so many factors of life, and there is still a great deal to learn about it. A young doctor the other day who was casting about for an object for research discarded tuberculosis because all the work to be done on it had been done! It is, perhaps, thus that some of us may have spoken many years ago, but it is increasingly clear that the more we know of the disease the more there is to know about it.

The number of people who die annually from tuberculosis—and the number in this country is about 50,000, or the equivalent of a county borough—are not, of course, the only sufferers from the disease. We shall not be far out if we reckon that for every death there are about five people ill with it. And they are ill for months or years. The length of time a patient lives after the first onset of symptoms has been variously estimated from twenty-one years to thirty-one months; but lately some more exact work has been done on this subject by Dr. Wurtzen of Denmark. His material included all the deaths from pulmonary tuberculosis at the Tuberculosis Department of the Oresund Hospital from April, 1906, to the end of 1919.<sup>1</sup> There were 1,032 men and 780 women, as well as 87 children. The mean duration of life for adults of both

sexes was 35.9—for men 37.1, for women 34.4—and only 11.9 months for children below the age of 15. He also made some investigations as to what degree sanatorium treatment influenced the prolongation of life, and he found the mean duration of life was 56.1 months, as compared with 35.9 of both sanatorium and non-sanatorium cases. Of course this comparison loses a good deal of value because of the selection of cases considered suitable for sanatorium treatment.

The mortality rate of tuberculosis has certainly been falling, so far as this country is concerned. But it has been steadily going down for the past 150 years, and we therefore cannot fairly put it down to all the extra work done and the attention paid to this most important of all diseases. This fall in mortality rate is mainly due to those causes which have helped to lessen the general mortality rate, such as the improved standard of living, housing, cleaner clothes, better food, and so forth. Incidentally, the invention of shoddy and other cheaper materials for clothes cannot have been without its effect in this direction. Dresses, for example, are no longer handed down from one generation to another, as they certainly were in the eighteenth and early nineteenth centuries. It is a great temptation, to which it is only too easy to succumb, to regard the special measures taken to deal with tuberculosis as the one chief cause of the reduction of tuberculosis mortality, and indeed, on the first glance, ordinary figures seem to offer an encouragement to this belief. But if, as someone has said, there is as much difference between domestic cleanliness and surgical cleanliness as there is between respectability and holiness, there is at least as much difference between ordinarily compiled figures and those of a careful, competent statistician. And on this last basis we have little reason, in England at any rate, to comfort ourselves. The real facts are, as shown by Ransome, that the mortality rate has been going down steadily since 1743, and Karl Pearson says:<sup>2</sup>

"We have to stretch our ideas of time a little, and we should realize the possibility of a typical epidemic curve in the frequency of phthisis. Indeed, the mortality from phthisis in England has been declining since 1838—that is, long before any special measures had been taken for the control of the disease, or segregation of the sources of infection—tuberculous human beings and animals—had been attempted."

Moreover, the fall in the death rate is not constant. It is really going up in countries like Germany and Russia, and in some primitive communities. It also rose quite definitely in women during the war, mainly, probably, as the result of their entry into factories in large numbers, the restriction of food being counted as a contributory factor as well. In the present state of our knowledge, which we are only too well aware is far from complete, we are justified in going on with all reforms that tend to improve public health in general—better housing, cleaner and more abundant food—and indeed with everything that helps to improve the health of each individual in the community. We have no doubt paid too much attention to the seed of the disease, as it were, without paying enough to the soil in which it is to grow. The dictum that no big eater ever caught consumption is really substantially true, and it certainly points to the desirability of seeing that the people's food is abundant enough, of the right kind, and as cheap as possible.

There is no doubt that for infection to take place association must be close and prolonged, and the recipient must be from one cause or another in a debilitated state of health so as to enable him or her to offer less resistance to the inroads of the disease. A recent case will probably be in the minds of most of us—*Collins v. Hopkins*, taken before Mr. Justice McCardie. In this case the plaintiff Collins took a house on October 26th, 1922, and left it the next day on the ground that it was infected with tubercle bacilli, and therefore not reasonably fit for habitation. The patient left the house six weeks before, on September 11th, and the danger, if any, must have been negligible, but the plaintiff's counsel made much of the house being dusty and dirty, though that is a fact very difficult to prove. Moreover, the medical attendant had neglected to notify the case to the medical officer of health. In giving judgement, a great deal was said by the learned judge which

approaches them. It is thicker in Scotland than in England, partly perhaps because the country is colder; but its local density of population is greater in the cities of Scotland, and domestic smoke pollution correspondingly more abundant, that is a condition which is surely much more capable of amendment than housing in general. Can it not be remedied by adopting smokeless methods of heat production in dwellings and factories? It is not necessary to-day to insist on the influence of the exclusion of sunlight by smoke in respect both of tubercle and of rickets. It is known to everyone.

Another question is whether any important racial and sociological changes have taken place and are taking place in Glasgow and the industrial west of Scotland. To what extent is the population losing by emigration to Canada and Australia and the United States men and women typically Scottish in character, of a sort which has been successful wherever it has penetrated? Can there be to a patriotic Scotsman a sadder sight on a Saturday afternoon than that of a great Atlantic liner passing down the Firth of Clyde loaded with emigrants bound for the new world, while the pleasure trippers on the paddle steamers look up and sing, with a quaver in their voice, "Better to be a poor man in my own country than a rich man in a foreign land." And he cannot be, will ye no' come back again? "And how far has immigration from Ireland, especially from Southern Ireland, replaced the population lost by emigration? To what degree is Glasgow becoming a Scotch-Irish community, and what are the results of the change on social order and general prosperity and public health likely to be?

These are by no means all the questions which arise in connection with this important subject. Much material now exists for elucidation of rural health conditions. Since county councils began their work, more than thirty years ago, the annual reports by their medical officers must have accumulated a mass of information well worth collection and analysis. These reports relate only to non-burgal areas, but any investigator would have to note that various thickly populated and industrial communities have elected to remain under county government rather than to municipalize themselves. Apart from such reservation the influence of climate on health could be suitably studied by means of the county reports. The lower rainfall and more bracing climate of the east of Scotland could be compared, in its effects on public health, with the much moister and more relaxing climate of the west. Likewise the higher temperature of the southern counties with the colder highland regions. The influence of insularity could be studied in the data for Orkney and Shetland and the Hebrides. The attention now given to infant and child welfare, the health of children at school, and maternity welfare, which to base comparison of activities and results as between area and area must be growing steadily, and should be utilized, both for commendation and for admonition.

Our purpose, as already said, is to ask questions, not to answer them; neither to praise nor to blame, but to urge the far-reaching implications of the comparisons between England and Scotland, and to suggest that there is abundant occasion and opportunity for valuable research into the health problems of Scotland. In these days there is too great a tendency to assume that research can only be conducted in a laboratory, but there is ample opportunity for field work of the best sort. The harvest is ready, and we hope the reapers also may be found.

## TUBERCULOSIS: THE PRESENT POSITION.

In this issue, which contains a larger number of pages than usual, are published the proceedings in the Section of Tuberculosis of the British Medical Association meeting at Portsmouth, under the appropriate presidency of Sir Henry Gauvain, who has done so much at the Cripples' Hospital and College at Alton and at Hayling Island for the non-operative treatment of surgical tuberculosis. This beneficent institution, rightly called after the late Sir William Treloar, whose recent death we deplore, was the home in this country of bacteriology, and it was therefore right and proper that the Section should discuss the artificial light treatment of lupus and other forms of tuberculosis, under the guidance of Dr. Axel Key of the Rinsen Institute at Copenhagen, and Dr. J. H. Sequeira of the London Hospital. The Section also considered the present position of the surgical treatment of pulmonary tuberculosis, with special reference to its infectivity. Dr. Olive Rietere's British Medical Association Lecture on some pitfalls in the diagnosis and treatment of pulmonary tuberculosis, and two contributions on the complement fixation test in tuberculosis, by Drs. A. T. Punch and A. Hope Gosse of the Brompton Hospital and by Dr. Arthur Sellers respectively, also published in this issue, add to the value of what has become a symposium touching on the several aspects of prevention, diagnosis, and treatment. We publish also records prepared by Dr. Leonard Williams of twenty-three cases treated by the serums and vaccines prepared by J. Spahlinger at his laboratory near Geneva. Lastly, in the course of a review of the fourth annual report of the Chief Medical Officer of the Ministry of Health, will be found some results of administrative experience summarized in the light of recent clinical observation with Sir George Newman's customary felicity.

Dr. Jane Walker's opening paper on the social aspects of tuberculosis bears witness to the difficulty of explaining the steady fall of the tuberculosis mortality rate during the last 150 years; for it tuberculosis is largely an industrial disease the conditions in this respect alone can hardly be regarded as more favourable since the industrial revolution which began at the end of the eighteenth century and led to the transfer of so large a proportion of the population from the country to towns. Many factors in the standard of living are no doubt concerned, and especially food, Indian statistics, rightly insisted. Incidentally Dr. Jane Walker suggested that the invention of cheap materials for clothes, thus obviating the importance of dress from one generation to another, may not have been without its influence. That for infection to take place massive dosage and close and prolonged association are necessary she illustrated in various ways.

Dr. H. Batty Shaw pleaded with no uncertain voice for the sterilization of tuberculous cows' milk, and for the removal of persons discharging bacilli from the neighbourhood of children, which is a possible step, and not from contact with other adults, which he admits to be impossible; if these conceptions were carried out he anticipated that tuberculosis would be stamped out, and expressed the opinion that other measures were not only useless but wasteful. He insisted on the importance of secondary infection in pulmonary tuberculosis, maintaining that without it tubercle bacilli are not discharged and hence do not follow a molar consolidation and excavations do not follow.

brilliance—people who are ornaments to any state or condition of life, and their lives have been saved for many years by sanatoriums. Also, in those places where second and third stage cases are not refused, the assistance afforded to their relations and friends has been incalculable. Not only is the spread of the disease in their own homes checked, but by removing the patient they are saved the great fatigue and anxiety of nursing, and have also more money for themselves to spend on food.

In sanatoriums, also, patients learn a great deal—not by often repeated lectures, or indeed in a mass at all, but by small talks and advice given individually, as well as the more general sensible outlook maintained. In adults, too, as with children, the finishing-up habit at meals, and the porridge habit, both of which are very strongly urged at most sanatoriums, are of incalculable value. As well, too, is the knowledge that the ordinary and therefore inexpensive foods are the ones that do most good. The pride always inherent in the person who has a small appetite receives a very wholesome check in any sanatorium. If this applies to adults, it applies doubly to children. If, as really seems certain, tuberculosis is contracted in childhood, though it may not make any definite appearance till adult life, it is of the utmost importance to so increase the resistance to the disease in early life as to give it little chance when the strain comes later on in life. Where a child shows signs of having contracted tuberculosis, he should have a sufficiently long period of really efficient treatment to give him a real chance of acquiring a lasting immunity. There is some good reason for believing that this is done in some cases, though no definite conclusions have so far been obtained. The dictum "once tuberculous always tuberculous" is very hard to fight, and for a person to have to give the history of having been in a sanatorium in early life when applying for life insurance, for example, is often very detrimental to him. Many obvious sufferers from tuberculosis are much better lives, as far as insurance is concerned, than are many non-tuberculous, because they have learned real wisdom in managing their lives, and this enables them to live longer.

We have seen that tuberculosis is on the decrease—that is, that there are really fewer cases than there were; not, I am inclined to think, that the case mortality is lessened. We still get the virulent type of case that seems capable of little or no amelioration, and which runs as rapidly fatal a course as formerly; but there are certainly fewer cases of all kinds, and this diminution in numbers is specially noticeable in children. It is probable that this decrease is due to many factors the relative importance of which we are really unable to judge. There is a steadily upward trend in the habits of the people in general; their habits are better, their manners are improved. There is, for example, far less spitting than there was, and there is far more cleanliness. I recently had twenty non-tuberculous children sent down to the sanatorium from a district in the East End of London where formerly the standard of living was lower than in any other area in the metropolis. All these children had had a warm bath the night before they came, and only one was flea-marked and that very sparsely, and no child had a verminous head. For these improvements we have to thank the school medical and nursing services. Then people live better; they certainly drink less. Alcoholic intemperance, and indeed intemperance of any kind, is a most potent factor in the contracting of tuberculosis, and it greatly diminishes the power of recovery of the intemperate. Publicans, as is well known, have a high mortality rate from tubercle. They also probably get massive doses in the way of infection as well as a diminished resistance consequent on their habits.

People have also better quality in food, and the cooking is improved. They have less arduous work, and more leisure in which to improve their minds. Incidentally the Workers' Educational Association and kindred bodies have been of untold value to the nation by helping people to use their leisure time aright. Then, too, the various coal strikes have perforce made people use smoke-consuming devices more and more for their cooking and warming,

and so they are breathing a far cleaner air than formerly. Again, labour-saving devices have helped to lessen the drudgery of life to a really large extent. All these things have their contributory effect on the prevention of tuberculosis.

With regard to the treatment of tuberculosis, we must see to it that the civilian part of the population has as good opportunities for treatment as has the ex-service man. We must make satisfactory provision for the wife and family while a man is away undergoing treatment, so that he may go at an earlier stage of his disease, and thus not only lessen the period of his treatment but also increase the probability of his complete recovery.

The one great thing that we must try to do for children as well as grown-up patients is to have a really effective after-care machinery, so that when the institution is left behind a friendly hand is held out to help and encourage the one-time patient when he takes up the battle of life again. The sanatorium should be linked up with the dispensary, which in its turn should be in touch with employers of labour as well as with organizations with funds at the disposal of the tuberculous person to help to supplement his earnings till such time as he is self-supporting. The question of what trade or employment he is fitted for is a very difficult one. Sometimes a sheltered trade, where the work can be arranged at such a speed as is within his powers, can be found. These arrangements, however, can usually only be met with in a colony and not in the open market. There are up and down the country colonies of various types and kinds that are attempting to deal with this side of the question, in some cases, as at Papworth and at Nayland (the sanatorium with which I am concerned), with a good deal of success.

What is known as the Framingham Demonstration was initiated in December, 1916. In Framingham, which is a town in Massachusetts of some 16,000 inhabitants, machinery has been organized for a twofold purpose:

"(1) To serve the general health needs of the community; and (2) to bring under observation all of the tuberculosis in the community, to apply the best known methods of treatment, to develop a comprehensive programme of prevention, and to organize most effectively the varied resources of the community for tuberculosis control, disease prevention and health creation."

A periodical examination of a large proportion of the inhabitants of the town, a census of all individuals in the town, covering matters of hygiene, housing, economic status, etc., a survey of tuberculous infection among cattle supplying milk to Framingham, are amongst the various activities that have been undertaken. Mr. Charles Hatfield is the secretary, and he gladly gives all the information in his power. The last report I have seen is dated February, 1921, and covers the first four years of working. It is a very interesting experiment, and on paper at any rate seems worthy of being applied to this country. Perhaps such an organization as the People's League of Health might be so constituted as to give most valuable help, if not actually to undertake this work.

In conclusion, there is no royal road to success with the tuberculosis problem any more than there is in any other subject of such great magnitude, and if the lines of advance outlined above seem rather humdrum and dull, I am convinced that it will be along such lines that future success will travel.

#### DISCUSSION.

Dr. H. BARRY SHAW (London) said that before he committed himself to any statements on the social aspects of the infectivity of tuberculosis he must endeavour to clear the ground on which he proposed to stand, and if the process of clearance sounded self-opinionated and wanting in elaboration, he asked his audience to remember that there was much to be said, and little time in which to say it. Tuberculosis was spread by tuberculous milk and by the emanations from human beings who were infected with the disease; therefore, if we could but stop these sources of

THE DENTIST  
MEDICAL JOURNAL  
531

that the experience gained in this operation, now the first time since the beginning of the war, has been of great value to the Government and the people.

THE SKULL OF SIR THOMAS BROWNE.

Some eighteen months ago it was resolved that the skull, preserved in the museum of the Norfolk and Norwich Hospital for some eighty years, should be replaced in the grave in the clove of St. Peter Mancroft, Norwich, from which it had been "knave" by a person described as an "acquisitive antiquary." But before this reposition

THE SKULL OF SIR THOMAS BROWNE.

preserved in the museum of the *Norfolk and Norwich Hospital* for some eighty years, should be replaced in the grave in the floor of the chapel of St. Peter Mancroft, Norwich, from which it had been "knave" by a person described as an "acquisitive antiquary." But before this reportation Sir Hamilton Balfour and other members of the staff of the hospital considered it desirable that the skull should be examined, and for this purpose sent it to Sir Arthur Keith at the Royal College of Surgeons of England. The story was told, with some preliminary observations, in our columns by Canon Meyer, the Vicar of the parish, on May 6th, 1922, and subsequently Sir Arthur Keith and Professor Karl Pearson announced that a full account of it would be published. This has been done, and the volume *Sir Thomas Browne: His Skull, Portrait, and Ancestry*, is now before us. The edition is limited to 200 copies at one guinea each, and the names of a few additional subscribers will be received by the Secretary of the Biometric Laboratory of the University College, London, W.C.1. The book is an enthralling possession. It contains a discussion on the skull and the portraits of Sir Thomas Browne prepared by Miss M. L. Tidley, a research worker trained in the exact methods of the Biometric Laboratory of University College, who has in this matter acted in consultation with Sir Arthur Keith, who contributes a short introductory note. Professor Elliot Smith has written a report on the endocranial cast. Miss Tidley has examined all the portraits supposed to be portraits of Sir Thomas Browne, and the volume contains thirty-five plates and a folding pedigree. On account of this last use of plates the cost of producing the volume has been large, but it is of quite unusual interest and is likely to become, to say the least, one of the curiosities of medical literature. The skull is of peculiar form, being unusually low in front and broad posteriorly; on this account some objections have been made to its ascription, but Miss Tidley has no hesitation in drawing from all the great mass of evidence she has collected the definite conclusion that it is the skull of Sir Thomas Browne, author of *Utriusque Medici*, and this opinion appears to be accepted by both Sir Arthur Keith and Professor Karl Pearson. It is confirmed by the discovery of a portrait of Sir Thomas Browne hitherto unknown. It is the property of Mr. Francis Wellesley, who has permitted its reproduction as the frontispiece to this volume; it was originally the property of Mr. Hammond L'Estrange of Hunstant, and is known as the L'Estrange portrait. It shows a man in early middle age, and a young woman. The portrait of the man was taken as of Sir Thomas Browne. The young woman is assumed to be his wife, and it is guessed that the picture was painted about the date of their marriage (1641), when she was 36 and she was 19. It was painted on an oak panel and shows in the man a head which "answers in every detail to what the skull would indicate as the appearance of the living head. The nose long and slightly aquiline, the cheek-bone projecting, the forehead normally broad at the level of the eyebrows, but retreating and narrowing abruptly." We hope to notice the monograph at greater length on some future occasion, but meanwhile would repeat that it is an enthralling possession, and as the edition is limited applications for copies should be made without delay.

A point was thus reached when further advance could only be gained by operation on an actual patient. This was performed on May 20th last on a girl, aged 12 years, suffering from mitral stenosis without cardiac waves, who had repeated attacks of severe haemoptysis. When she was examined after admission the pulse rate was 126, the systolic pressure 99, and the diastolic pressure 64 mm. Hg. The electrocardiogram showed right ventricular preponderance and exaggerated aortic waves, the ventricular complexes being otherwise normal. The operation was performed under ether, the child being in a semi-erect position with the electrocardiographic leads and the blood pressure apparatus connected up. The technique followed was Duval-Barast's medium thoraco-abdominal pericardiotomy; after opening the pericardium and division of the posterior pericardium and diaphragm towards the suspensory ligament, the pulse had dropped from 180, which it had reached at an earlier stage of the operation, to 120, and the blood pressure from 110 to 50 systolic, the estimations being at times almost impossible. The heart at once responded to 1/2 c.cm. adrenaline chloride dropped on its surface, followed by the right, and the valvulotome—an instrument somewhat similar to a tenotomy or a slightly curved needle, familiar in its use in the experimental researches—was plunged into the left ventricle at a point about one inch from the apex, and pushed upwards for about two and a half inches until it encountered what seemed to be the mitral orifice; it was then turned mesially and a cut made in valve, the resistance to be the aortic cusp of the mitral valve, the resistance encountered being considerable; with a rapid turn of the knife a cut was made in the opposite side; the knife was then quickly withdrawn, and mattress sutures already in place were tied over the point where the knife had been inserted. There was absolutely no bleeding. At the termination of the operation, which lasted one and a quarter hours, the pulse rate was 140, the respirations 40, the systolic blood pressure 80, and the diastolic 40. For forty-eight hours there was severe sternal pain with respiration which necessitated a liberal use of morphine; signs of post-operative pulmonary complication of the right upper lobe appeared also, but by the fourth day the improvement was satisfactory. Pericardial friction was subsequently detected; the diastolic thrill and murmur, present before, were diminished, but this diminution may have been due to pericardial effusion; the apical systolic murmur was increased, as it from greater insufficiency of the valve due to the operation. As the date of publication was June 28th, the authors, who must be sincerely congratulated on this brilliant operation, are cautious in avoiding any statement as to the benefit that the patient has received, but they feel

unfashionable truths? They had only recently—as Dr. Jane Walker had reminded them—been shown how confused medical opinion had become by reading the conflicting evidence given by their colleagues in the law courts. He was sure that a great part of the confusion was due to the fact that some of them still held by the old convention of the unity of tuberculous consumption and tuberculous phthisis and turned a deaf ear to those who would maintain that the process was a dual or multiple one. Could it be wondered at that the public, seeing their confusion, doubted their convictions and ridiculed Acts of Parliament based upon them? The spread of tuberculosis would be countered by feeding children, when it was necessary, with cow's milk which had been sterilized, by the segregation, maybe permanent, of those who discharged tubercle bacilli, and by the temporary segregation of those who were suffering from non-tuberculous respiratory infections. It was possible that the infection of the young with a certain amount of tuberculosis, bovine or human, might be beneficial; but he suggested that, until they knew what amount of infection was beneficial and what amount was harmful, they should try rather to prevent all infection with any form of tubercle bacillus.

Dr. J. E. CHAPMAN (London) said that in the latter part of her interesting paper Dr. Walker called attention to the need for developing really effective after-care machinery in connexion with the schemes for combating tuberculosis. It was to this matter that Dr. Chapman wished to direct attention. Tuberculosis in its more chronic forms was a disease which extended over long periods; periods of ill health tended to alternate with periods of fair health and even in the most favourable cases the duration of treatment was considerable. The wage-earning capacity of the patient was consequently extinguished from time to time and in many cases there was a permanent reduction of earning capacity. The effect of these conditions upon the family was quickly felt, unless some savings had been laid by for a rainy day, if the patient happened to be the breadwinner or the mother of the family, and the whole family tended to drift into a state of poverty. The Chief Medical Officer of the Ministry of Health said in his Annual Report for 1921:

"Poverty is an important factor in the causation of tuberculosis, and tuberculosis in turn is itself a cause of poverty. The vicious circle thus formed can be broken by action on sociological lines as well as by appropriate medical treatment. 'Early treatment' of the sociological problems arising from the occurrence of a case of tuberculosis in a family is frequently as important in the interests of the patient and the family as the medical treatment of the individual sufferer."

The occurrence of tuberculosis in a working-class family, particularly if the patient was an adult, was frequently an economic disaster. What results could they expect from the best medical treatment if the patient and family were drifting into a state of poverty and the patient was probably unable in consequence to follow out adequately the treatment prescribed? Could they expect patients, who had responded well to treatment in a sanatorium, to retain their improved health if they had to return to unsatisfactory home conditions resulting in part from straitened circumstances? Were the underfed children of the family likely to resist possible infection satisfactorily? Care committees, by attending to the economic problem in the cases of individual sufferers and their families, could frequently assist very materially in rendering treatment effective, in reducing the risk of relapse, and in minimizing the danger of spread of infection. The Departmental Committee on Tuberculosis—the Astor Committee—recognized the need for care committees and stated in its Interim Report published in 1912:

"The effectiveness of the work of the dispensary can be greatly increased by the organization of voluntary care committees formed of representatives from the local authorities, boards of guardians, insurance committees and from all charitable and social work organizations in the district. In this way all available agencies can be linked up and any extra assistance such as additional food, change of air, clothing, better home conditions, more suitable occupation, etc., that may be needed to enable patients to benefit to the fullest extent from the treatment provided may readily be secured."

The Local Government Board drew the attention of

counties and county boroughs to the above statement in a circular issued in 1915, and added:

"It appears to the Board to be important that Committees such as the Departmental Committee recommended should be organized in every area for which a scheme for the treatment of tuberculosis has been adopted, and, inasmuch as the work of these committees should relate to the whole community, their organization should be undertaken under the general direction of the councils of counties and county boroughs, who are responsible for the schemes of treatment."

Unfortunately a variety of circumstances—the war, the inherent difficulty of the work, and the scarcity of trained social welfare workers—had led to the development of these committees being slow. In some areas, however, excellent care committees had been established, and he thought that he could indicate the nature of their work most satisfactorily by quoting examples of cases which had been dealt with by them. Before he referred to these cases, however, he thought it might be useful to set out one or two important principles which should govern the action of care committees. In the first place the aim of the committee should be to help the patient to help himself rather than to allow him to be dependent on others. The care committee should not be a kind of public assistance committee doling out financial help, but a body which would consider in detail the needs of each patient and his family and determine how best they could help him to regain or maintain economic independence. It would, however, sometimes be necessary for the committee to give material assistance, but such assistance should only be given with the greatest circumspection and as a preliminary to the execution of a carefully arranged plan by which the patient might be expected ultimately to be able to depend upon his own resources. When material assistance was needed, it was desirable, in order to prevent overlapping of effort, for the committee to bring the patient into touch with the appropriate national or local agency which could meet the need. In this way the British Red Cross Society, the United Services Fund, Charity Organization Societies, Invalid Children's Aid Societies, Juvenile Employment Committees, and many other organizations, whose spheres of activity would be known to the committee, could render invaluable aid. In order to secure complete efficiency it was, however, usually desirable, particularly in the provinces, where the network of social welfare organizations was not so extensive as in London, for the committee to possess some funds to enable them to help cases which could be dealt with by existing organizations. Much excellent work could, however, be done by a committee which possessed no funds for this purpose, as will be seen from the cases he proposed to quote. In the second place, the unit with which the committee should deal should be the family and not the individual member who was suffering from tuberculosis. Any action which improved the circumstances of the family would have its proper effect upon the patient and vice versa. In the third place, action should be taken when necessary before the circumstances of the family had become disorganized, on the principle that prevention was better than cure. The Ministry of Health dealt with these last two points in a recent circular issued to Metropolitan Borough Councils as follows:

"The occurrence of tuberculosis in a single member of a family may have a serious effect upon the social and economic circumstances of the family as a whole, and it is consequently essential that the unit with which the care committee should deal should be the family and not the individual patient. The early consideration of the economic effect of the occurrence of tuberculosis in a household is as important as the early diagnosis of the disease in the individual. The primary duty, therefore, of the committee should be to consider the economic position of the family of every patient suffering from tuberculosis as soon as he comes within the purview of the dispensary scheme, and to render such advice and assistance as circumstances of the case dictate, with a view to enabling the family to adjust their circumstances to the new conditions, to maintain their economic independence and to derive the fullest possible advantage from the medical treatment prescribed."

He then quoted a number of actual cases, taken from the records of a number of Care Committees, to illustrate these principles in action:

Case 1.—The patient lived with a widowed mother, sister and three brothers, with whom he shared a bed. The Care Com-

ago there were four beds, now there were fifteen, and the demand was for more. The number of patients so far admitted was 150, and 113 operations had been performed. She applied to the district to support the institution and to rally round Sir John. Lynn-Thomas and the other members of the medical profession in the district who were working at and for the hospital. The mayor, after mentioning that Sir John Lynn-Thomas had prevented all his financial statements to the hospital, and also the nucleus of a medical library, called upon him to speak. Sir John Lynn-Thomas said that the hospital still wanted a research department. If the causes of diseases were discovered that prevention would follow almost automatically. Cardigan and done better than any town in Wales in regard to the hospital, and he knew no town in England which had done so well. The hospital, he said, had a flat roof, which could be used for the sun and open-air cures, as well as a good garden, with exposure to the south. Votes of thanks by Sir John Evans to Mrs. Lloyd George were passed by acclamation.

Within the last few years there have been important changes in the medical journals of Scandinavia. Before the war each of the Scandinavian countries had its own medical journals published in the language of the country. The Swedes and Finns wrote in Swedish, and the Danes and Norwegians in Danish and Norwegian. The worst feature of this arrangement was the isolation it entailed; an important discovery published in Norwegian might easily be overlooked by the rest of the world, and when the same discovery was made some years later in another country no credit was given to the author, whose publication still languished in the obscurity of a Scandinavian language. More than one instance of such an oversight could be given, and in consequence of this difficulty Scandinavian workers were beginning some years ago to publish their observations abroad, notably in Germany. This procedure also had its drawbacks. The bulky and numerous journals of pre-war Germany proved a capacious burying-ground in which the identity and nationality of the foreigner were often lost. To meet these two difficulties—that of publication in an unfamiliar tongue or in a foreign journal—the leading Scandinavian medical authorities decided on a wise compromise which consists of pooling all original Scandinavian work in a series of special journals *Acta*, in which articles are published in one of the three languages, English, French, or German. In addition to *Acta Medica Scandinavica* there are various other *Acta*, including *Acta Chirurgica*, *Acta Radiologica*, *Acta Obstetrica et Gynecologica*, and *Acta Otorhinolaryngologica*. Each *Acta* is conducted by an editor and a staff of associate editors, and the journals appear at irregular intervals according as the supply of material and other considerations permit. The standard of these publications is high, and already authors in Holland, Germany, and the countries carved out of the old Austrian Empire have sought the hospitality of their columns. It is not difficult to explain the reasons for the high standard of Scandinavian medical work in general and publications in particular. The Scandinavian is a good linguist, and it is rare to find one who holds an important hospital appointment and who cannot read English, French, and German. It follows that he is more likely to be conversant with medical research throughout the world than many of his English, French, and German brethren. Another advantage of belonging to a small country is the side position confers. The development of the young Scandinavian scientist is seldom stunted by some dominant position confers. The advantage of the young bird's-eye vision, perspective, and freedom which this out-

ing personality in his own country. In Germany, for example, there have been times when not to follow among Philistines. Feeling at liberty to pick and choose at their own sweet will the Scandinavians have never committed themselves wholesale to any special school of thought, and, while seeking inspiration from abroad, they have not been slow to pursue independent research at home. Yet another factor contributing to the value of their publications is the transparency of the scientific fabric in these northern countries. Everyone knows everyone else, privacy of scientific work is therefore almost impossible, and the publication of pseudo-original articles is likely to bring the author more ridicule from the initiated than kudos from the crowd.

Dr. Cecil Bull, in a note published at page 533, describes some of the merits and some of the disadvantages of medical practice as it is now conducted in North America. Dr. Bull was on the general staff of the Mayo Clinic at Rochester, Minnesota, for two years, and during that period visited other cities and clinics. He considers that the modern intensive training of the medical student in America is not altogether satisfactory in fitting men to become country practitioners, because they feel starved intellectually when not in touch with laboratories equipped with the elaborate instruments to which they have been accustomed, and with a medical society and a medical library. Moreover, they are liable to lack self-reliance. On the other hand, local medical societies are numerous, the output of medical literature is enormous, and much examination and tests of all sorts. Hence the development of much specialism and a tendency, perhaps, to over-examine the patient. The American medical profession is keen on research, and in its pursuit a vast amount of detailed observation is accumulated which, no doubt, is of very great value provided the observer is not "prevented from seeing the wood for the trees." In clinics such as the Mayo Clinic, with its clerical staff, the doctor is relieved of keeping notes, the filing of records, and much of his correspondence. But he may become a slave to routine, and there must be a temptation to neglect the personal factor in his patient. It is interesting to compare Dr. Bull's article with "Notes on a tour of the principal hospitals and medical schools of the United States and Canada," by Mr. A. E. Webb-Johnson, which have been printed for private circulation by Mr. S. G. Asher, chairman of the council of the Middlesex Hospital Medical School. Mr. Webb-Johnson arrived at New York on February 18th last and left on March 31st. Between those dates he visited Philadelphia, Baltimore, Washington, Cleveland, Chicago, Rochester, Toronto, Ottawa, Montreal, Quebec, Boston, and New York. His notes are a record of an exciting round of hospitals, clinics, laboratories, dinners, teas, meetings, lectures, stockyards, and slaughterhouses. Mr. Webb-Johnson, like Dr. Bull, observed that the undergraduates in America does not have a long clinical training with individual patients, but is instructed more by classes. Consequently, after getting his degree he requires the clinical experience which our students get while acting as clerks and dressers; and the post-graduate problem in America is the provision of courses directly after qualifying rather than to cater for general practitioners who wish to be brought up to date. Mr. Webb-Johnson was convinced of the advantage of special departments properly developed in general hospitals over the system which prevails too much in London of general hospitals with meagre special

MUTHU (Mendip Hills Sanatorium) agreed with Iker that our knowledge of tuberculosis was still in its infancy, and that many problems connected with it were yet unsolved. One reason for our lack of knowledge of uncertainty with regard to tuberculosis might be that we had been putting the cart before the horse and had attracted our attention on the microbe rather than on the man. It was, after all, the chief actor in the drama. There is no doubt that the study of social conditions of life, their daily life and their habits, their food and their occupation, their housing accommodation—human factors helped to give a truer insight into the causation of tuberculosis and its prevention than any other factor. Tuberculosis was, to a great extent, a social, a domestic, and industrial disease. While it could not easily be eradicated in the fresh air, in the open country, where there was good nutrition and the best hygienic surroundings, it flourished in slums and overcrowding, in underfed children, in poverty and destitution, which were the outcome of the social system. The economic history of tuberculosis showed a high rate of mortality during the last sixty or seventy years. It ought to be remembered that periods of war, depression, industrial and economic stress, were followed by a period of improvement, a lower standard of living, poverty, and an increased mortality rate from tuberculosis; whilst times of revival of trade, industrial prosperity, continuous improvement, cheapening of food and sanitary reforms, contributed to the happiness and well-being of the people and diminished the death rate from phthisis. Even the sharp increase in tuberculosis mortality during 1914 to 1918 showed a close relation between social and economic conditions and the death rate of phthisis. Social environment, then, was an important part in the incidence of tuberculosis. Social, economic, and hygienic environment could be grouped under three heads: insufficiency of fresh air; light; insufficiency of housing accommodation, leading to overcrowding; insufficiency of food or ill balanced diet leading to malnutrition. Facts observed from all over the world showed a positive correlation between the social and the death rate from tuberculosis. In London, the proportion of overcrowding was under 7.5 per cent. the death rate of phthisis was 1.044; but when it was 5 per cent. or more the death rate rose to 2.052. In poor and crowded Finsbury the death rate for phthisis was 2.14, in spacious and well-to-do Hampstead it was 0.63. In Glasgow, among families living in one room the phthisis death rate was 23.3, among those occupying two rooms it was 18.9, three rooms 14.3, and in four rooms it was reduced to 12.7. So in Dundee: in houses of one room the death rate from pulmonary tuberculosis was 10,000, in two rooms 64, in three 55.2, in four rooms and upwards 32 per 10,000. It was seen, therefore, that the smaller the accommodation the greater was the death rate, and the larger the accommodation the smaller the mortality from tuberculosis. In India he had observed the same thing. Crowded Bombay presented a high death rate from tuberculosis than Bangalore with its open cities. Among Mohammedan women, who were confined in ill ventilated zenanas, the death rate was three times as high as among men. In fact, the purdah system was observed the greater the mortality, as among Mohammedan women; and it was not enforced, as among the Burmese women, even lower than among men. In England the death rate from phthisis was higher among males than females, but when they were employed in industrial occupations they involved bad hygienic surroundings. But if, as in the late war, the females were subject to the same conditions of occupation, the mortality rate was the same or higher than males. Also, as Dr. E. L. Collis had said, if an industrial environment was replaced by a rural environment, as in Ireland, which meant a change in fresh-air conditions, there was no difference in the incidence of tuberculosis between males and females. Whether in India or England, whether among males or females, whether in sedentary or industrial occupation, the death rate of tuberculosis was influenced by the extent of overcrowding and vitiated atmosphere where people lived crowded and where their bodies were deprived of the

vivifying influence of fresh air and sunlight. On the other hand, in Edinburgh, where certain insanitary areas were replaced by new buildings which admitted plenty of fresh air and light, the death rate for phthisis fell from 45 to 15 per 1,000; while in Liverpool, in the new healthy areas with practically the same population, it fell from 4 to 1.9 per 1,000. But overcrowding was only one of a group of social evils which clustered round tuberculosis. It was closely associated with and was a symptom of poverty. The greater the poverty the greater was the tendency for the poor to crowd themselves into two- or one-room tenements. Dr. Menzies truly said the other day that the most important factor in connexion with tuberculosis was the food question. In India one of the three great determining factors in the incidence of tuberculosis was the hopeless state of poverty of millions of people (the other two factors were overcrowding and insanitation), which so undermined their stamina that they fell victims literally in thousands to any epidemic or disease that came along their way. Dr. Muthu had elsewhere recorded that India lost a million people annually from the scourge of tuberculosis alone. Coming nearer home, it was found that Germany, Austria, and other mid-European countries furnished evidence on a large scale of a great increase in tuberculosis mortality from chronic starvation and malnutrition. The German physicians were so impressed with the effects of underfeeding that Professor Kayserling, one of the foremost authorities in Germany, confessed that tuberculosis should be regarded primarily not as an infectious disease, but as a disease of nutrition, to be controlled much more by feeding than by preventing infection. The dictum to which Dr. Walker had alluded—that no big eater ever caught consumption—seemed to be true to a very large extent. B. S. Warren of America found, in common with many other workers, that low wages went hand in hand with high tuberculosis mortality, for low wages meant poor food, poor housing, and deficient nutrition. All these deficiencies, whether they were of fresh air or light, of housing accommodation or of nutrition, or restful surroundings, tended to lower vitality and to reduce the resisting powers, and brought about a faulty metabolism, which in turn prepared a soil favourable to infection. He had always considered that soil was more important than seed in the incidence of tuberculosis, and that infection was rather an effect of a poor soil, whether it were in man or beast. Dr. Walker had made a reference to the milk question. In India, where Dr. Muthu had recently travelled some hundreds of miles visiting many important cities on a tuberculosis mission, he found that tuberculosis among cattle was very scarce, that children were mostly breast-fed, that many Indians drank little or no cow's milk, and when they did they invariably had it boiled before use, and yet tuberculosis was very prevalent in many parts of India, and was increasing. It was only by knowing facts like these and comparing notes with other countries that we could enlarge or modify our knowledge concerning the disease. Tuberculosis was, therefore, intimately associated with social and economic evils which pressed upon a large mass of population and which opened up large issues, such as fair wages, unemployment, poverty, slums, overcrowding, etc. Sir Douglas Powell had said that the prevention of consumption involved a much wider issue than the circumvention of the bacillus. No doubt open-air sanatoriums had done much good work in this country in bringing about an arrest of the disease in a large number of cases, and in educating the patients and their friends in the right way of living. For the prevention of tuberculosis the State should go further and make an earnest attempt to initiate social reforms to improve the general health of the people. For it was not so much by destroying infection as by attacking boldly the social evils of the present day, by raising the standard of living, by improving the well-being of the people, and thus increasing their resisting powers, that we could hope to eradicate tuberculosis in the near future.

Dr. S. VERE PEARSON (Mundesley Sanatorium) said that notification was largely ineffective in that it was incompletely carried out, especially in point of time, and was not put to

care and all-day rest cures. When seen, in November, 1914, she had cough, abundant expectoration frequently blood-stained (tubercle bacilli present), slight pyrexia, palpitation, anaemia, emaciation 1 st. 7 lb., much dyspnoea, pain in chest, vomiting. There were signs of extensive infiltration of both lungs with cavitation at the right upper lobe. Spahlinger's vaccine treatment was commenced in November, 1914. In June, 1915, the cough and expectoration had diminished by two-thirds, the dyspnoea was less troublesome, weight unchanged, indigestion and anorexia stopped, activity in chest greatly diminished. In October, 1915, the patient was still showing general improvement when she suddenly died of amyloid disease. Vaccine treatment seemed to improve the pulmonary condition very materially, but it could do nothing for the degenerative process resulting from fifteen years of disease.

## CASE 10.

A. B., clerk; a pale youth, aged 21. Comes from tuberculous stock; grandmother and brother died of pulmonary tuberculosis; sister, aged 13, and brother, aged 27, died of generalized tuberculosis. The patient contracted bronchitis in 1908; ever since he has been weak and never able to get rid of his cough. During the summer of 1911 he had a second bad attack of bronchitis, and a third one during the summer of 1912. He was treated with rest, creosote, and tonics. In the autumn of 1914 a gland appeared on the right side of the neck, and in December it had greatly enlarged. When first seen in December, 1914, he had cough, expectoration (tubercle bacilli present), night sweats, great lassitude, anorexia, clubbing; he had lost 1 st. 4 lb. during the last six months. There were signs of scattered disease in both lungs. A gland was punctured, and tubercle bacilli found in pus. This glandular strain showed an unusual virulence in the laboratory tests. Spahlinger's treatment was started in December, 1914. Serum was injected into the gland and a few vaccine injections given subcutaneously. On May 31st, 1915, the night sweats, lassitude, indigestion, insomnia, and anorexia were entirely gone. There were no active signs in the chest. The patient had gained considerable weight. Believing himself cured, he discontinued the treatment. In August, 1915, a little swelling appeared on the right side of the neck. Vaccine treatment was resumed on August 14th, 1915, and continued until February 6th, 1916, when there were no active signs in chest, no cough, and no sputum, the weight was above normal, and the glands had disappeared. Discharged. In 1923 there was no relapse whatever since treatment was stopped seven years ago. The patient has been able to work uninterruptedly from the beginning of 1916 down to the present day. There is no trace of active disease. The frequent attacks of bronchitis and indigestion, which used to be very troublesome previous to Spahlinger's treatment, have entirely disappeared. He had influenza once in 1919, but it only lasted three days. He is now apparently quite well.

## CASE 11.

J. D., a thin youth, aged 21; shop assistant. History of bronchitis and pleurisy in March, 1913. Cough and sputum ever since. Sanatorium treatment. Discharged improved. When first seen, in December, 1914, he had a cough, expectoration (tubercle bacilli present 20 to 30 per field), emaciation, sweating, tachycardia, dyspnoea, melaena, clubbing. Signs of infiltration extending throughout left lung with massive disease at base and scattered infiltration in right lung. Spahlinger's serum treatment started in December, 1914. On April 3rd, 1915, the patient was much improved. During 1915-16 he had several courses of partial serum. In 1917 there was no evidence of active disease, weight normal, general condition very satisfactory, still some dyspnoea; discharged. In June, 1921, there was evidence of recrudescence of symptoms; tubercle bacilli in sputum, emaciation 12 lb., signs of activity in left lung. Partial serum treatment resumed. At present there is no evidence of active disease. The patient has a little sputum in the morning, but all the examinations for bacilli made in 1923 have been negative. Physical signs dry; weight above normal; still some dyspnoea. He has been able to work uninterruptedly since 1916, even in 1921 during the period of recrudescence of symptoms.

## CASE 12.

M. P., a thin, anaemic woman, aged 23; shopkeeper. History of succession of colds, cough, etc., for two years. Pain at right apex behind. When first seen, in March, 1915, she had cough, expectoration (tubercle bacilli present); emaciation 13 lb. in last few months. Signs of infiltration at both apices. Spahlinger's vaccine treatment was commenced in March, 1915. In November, 1915, physical signs dry. In July, 1916, there was no evidence of active tuberculosis; no cough and no sputum for several months. Discharged. In 1923 the patient is very well; she has been engaged in normal work since 1916.

## CASE 13.

G. P., aged 26, mechanic. Sister suffering from abdominal tuberculosis. Pleurisy in 1900 and again in 1911. History of pulmonary tuberculosis. When first seen, in May, 1915, he had cough, abundant expectoration frequently blood stained (tubercle bacilli present), pyrexia, loss of weight 1 st. 10 lb., haemoptysis, night sweats, dyspnoea, palpitations, weakness, clubbing. Signs of infiltration of the whole of left lung, with large cavity at apex, and signs of softening in upper lobe, also infiltration of right lower lobe. Spahlinger's treatment was commenced in May, 1915. In August the patient was able to resume his work, which he had given up four years previously. In November, 1915, condition improved, afebrile, expectoration diminished by 80 per cent.; still a few moist sounds in the left lung, and tubercle bacilli scanty; increase in weight 1 st., treatment stopped. Resumed in June, 1916, and continued until October, 1916, when the patient left for France much improved.

## CASE 14.

B. B., an extremely debilitated man, aged 35; shopkeeper. History of pulmonary tuberculosis. When first seen, in May, 1915, he had cough, expectoration (abundant purulent tubercle bacilli present, 30 to 40 per field), pyrexia, tachycardia, emaciation 13 lb., profuse night sweats. Signs show infiltration with softening in both upper lobes. Spahlinger's serum treatment was commenced in May, 1915. In May, 1916, there was great improvement; sputum scanty, signs in chest practically dry, weight normal; the patient resumed work; discharged. In 1918 he had a bad attack of influenza. In 1919 a second attack of influenza. Died.

## CASE 15.

J. L., aged 44; insurance agent. Pulmonary tuberculosis diagnosed in 1896. Sent to Switzerland in 1906. Tubercle bacilli constantly present in sputum. When first seen, in October, 1915, he had cough, profuse expectoration, occasionally blood stained, loss of weight. In spite of various treatments during the last twenty years no real improvement took place, and tubercle bacilli have always remained present. The patient was able to do light office work. Signs of scattered bilateral infiltration. Spahlinger's vaccine treatment was commenced on October 13th, 1915, and continued during a period of eight months, while the patient was attending his business. Having completed his course of vaccine treatment, he was discharged on June 17th, 1916, much improved. Still a trace of sputum with tubercle bacilli present. Signs in chest practically dry. In June, 1923, clinical examination and x rays show scar tissue in both lungs, but no evidence of active disease. There is a little cough and phlegm in the morning, but from 1917 down to the present time the sputa show no tubercle bacilli. The patient had a severe attack of influenza in 1920 but no bacilli could be found. He is now in excellent health, and has been engaged in active work for the last six years, although he has had no treatment since 1916.

It is interesting to note that some vaccine cases, such as the above, after having completed a course of vaccines, were discharged while tubercle bacilli were still present in their sputa. These bacilli subsequently disappeared without any further course of treatment, showing that the vaccines had thoroughly roused the patient's resisting power. It is well to remember that the conversion of diseased areas into cicatricial tissue takes time.

## CASE 16.

H. B., a thin, anaemic man, aged 30; nurse. Comes from tuberculous stock. History of frequent colds, bronchitis, cough, etc., during previous year. When first seen, in June, 1916, he had cough, expectoration (tubercle bacilli present), slight pyrexia, dyspnoea on exertion, tachycardia, emaciation 5 lb., pain in chest on right side. Complaints of chronic laryngitis (non-tuberculous), no appetite, lassitude. On the nose there was a tuberculous lesion which had resisted all previous treatments. Signs of infiltration at left apex and hilus. Spahlinger's vaccine treatment was started in June, 1916. In November, 1916, the symptoms were apparently quiescent, and the general condition much improved; the tuberculous lesion on the nose was cured. Discharged. The patient remained at work during the whole period of treatment. In September, 1922, there was no evidence of disease, no cough, no sputum, weight normal. Since discharge (end of 1916) the patient has worked as masseur in a Turkish bath (twelve hours daily), and notwithstanding the strenuous work has had no relapse. At present the patient is living abroad and is unavailable for examination; he writes that he is well and working.

## CASE 17.

H. M., man, aged 34. History of chronic pulmonary tuberculosis treated in sanatoriums, sea voyage, etc. Improvement after tuberculin injections. Served during the war and had several attacks of haemoptysis. When first seen, in May, 1921, cough was very troublesome, expectoration purulent, profuse (tubercle bacilli present, 100 per field), temperature 102°, pulse 100 to 120, haemoptysis, loss of weight 1 st. 10 lb., sweating, much dyspnoea, intercostal pain, clubbing. Signs of extensive infiltration in both lungs, mainly on the right side, with signs of softening at both apices; large cavity in right upper lobe, cavity at left apex and at apex of left lower lobe. Spahlinger's partial serum treatment was commenced in May, 1921, when the patient's condition was very critical. Serum was given subcutaneously and by mouth. In July, 1921, the condition was much improved, but a large area in the right lower lobe was still very active. In August, 1921, activity had apparently stopped, the temperature was normal, cough and expectoration diminished by two-thirds; the patient was able to get about. In November, 1921, there was an increase in weight of 1 st. 4 lb. In February, 1922, the patient stopped treatment and went abroad much improved, in spite of an attack of influenza. In 1923 the patient is leading a normal life.

## CASE 18.

W. K., a pale youth, aged 19; sailor. History of pneumonia in October, 1920; haemorrhages. Tuberculosis diagnosed in February, 1921, when the sputum showed tubercle bacilli to be present. When first seen, in May, 1921, he had cough, expectoration abundant, purulent, often blood stained (tubercle bacilli present 2 to 3 per field), frequent haemoptysis, emaciation 11 lb., night sweats, dyspnoea, diarrhoea, anorexia; temperature 102.2°, pulse 100 to 110. Signs of extensive infiltration of right lung and scattered foci in left. Involvement of larynx. Spahlinger's partial serum treatment was commenced in May, 1921. In January, 1922, the chest was dry and he was able to resume work. In May, 1922, there was no

As a result of the appeal for the British Empire Cancer Campaign nearly £55,000 has now reached the offices of the British Red Cross Society at 19, Berkeley Street, W.1. More than half the total number of subscriptions have been £10 or £20, £30, £40, £50, £60, £70, £80, £90, £100, £150, £200, £250, £300, £400, £500, £600, £700, £800, £900, £1,000, £1,500, £2,000, £2,500, £3,000, £4,000, £5,000, £6,000, £7,000, £8,000, £9,000, £10,000, £15,000, £20,000, £25,000, £30,000, £40,000, £50,000, £60,000, £70,000, £80,000, £90,000, £100,000, £150,000, £200,000, £250,000, £300,000, £400,000, £500,000, £600,000, £700,000, £800,000, £900,000, £1,000,000, £1,500,000, £2,000,000, £2,500,000, £3,000,000, £4,000,000, £5,000,000, £6,000,000, £7,000,000, £8,000,000, £9,000,000, £10,000,000, £15,000,000, £20,000,000, £25,000,000, £30,000,000, £40,000,000, £50,000,000, £60,000,000, £70,000,000, £80,000,000, £90,000,000, £100,000,000, £150,000,000, £200,000,000, £250,000,000, £300,000,000, £400,000,000, £500,000,000, £600,000,000, £700,000,000, £800,000,000, £900,000,000, £1,000,000,000, £1,500,000,000, £2,000,000,000, £2,500,000,000, £3,000,000,000, £4,000,000,000, £5,000,000,000, £6,000,000,000, £7,000,000,000, £8,000,000,000, £9,000,000,000, £10,000,000,000, £15,000,000,000, £20,000,000,000, £25,000,000,000, £30,000,000,000, £40,000,000,000, £50,000,000,000, £60,000,000,000, £70,000,000,000, £80,000,000,000, £90,000,000,000, £100,000,000,000, £150,000,000,000, £200,000,000,000, £250,000,000,000, £300,000,000,000, £400,000,000,000, £500,000,000,000, £600,000,000,000, £700,000,000,000, £800,000,000,000, £900,000,000,000, £1,000,000,000,000, £1,500,000,000,000, £2,000,000,000,000, £2,500,000,000,000, £3,000,000,000,000, £4,000,000,000,000, £5,000,000,000,000, £6,000,000,000,000, £7,000,000,000,000, £8,000,000,000,000, £9,000,000,000,000, £10,000,000,000,000, £15,000,000,000,000, £20,000,000,000,000, £25,000,000,000,000, £30,000,000,000,000, £40,000,000,000,000, £50,000,000,000,000, £60,000,000,000,000, £70,000,000,000,000, £80,000,000,000,000, £90,000,000,000,000, £100,000,000,000,000, £150,000,000,000,000, £200,000,000,000,000, £250,000,000,000,000, £300,000,000,000,000, £400,000,000,000,000, £500,000,000,000,000, £600,000,000,000,000, £700,000,000,000,000, £800,000,000,000,000, £900,000,000,000,000, £1,000,000,000,000,000, £1,500,000,000,000,000, £2,000,000,000,000,000, £2,500,000,000,000,000, £3,000,000,000,000,000, £4,000,000,000,000,000, £5,000,000,000,000,000, £6,000,000,000,000,000, £7,000,000,000,000,000, £8,000,000,000,000,000, £9,000,000,000,000,000, £10,000,000,000,000,000, £15,000,000,000,000,000, £20,000,000,000,000,000, £25,000,000,000,000,000, £30,000,000,000,000,000, £40,000,000,000,000,000, £50,000,000,000,000,000, £60,000,000,000,000,000, £70,000,000,000,000,000, £80,000,000,000,000,000, £90,000,000,000,000,000, £100,000,000,000,000,000, £150,000,000,000,000,000, £200,000,000,000,000,000, £250,000,000,000,000,000, £300,000,000,000,000,000, £400,000,000,000,000,000, £500,000,000,000,000,000, £600,000,000,000,000,000, £700,000,000,000,000,000, £800,000,000,000,000,000, £900,000,000,000,000,000, £1,000,000,000,000,000,000, £1,500,000,000,000,000,000, £2,000,000,000,000,000,000, £2,500,000,000,000,000,000, £3,000,000,000,000,000,000, £4,000,000,000,000,000,000, £5,000,000,000,000,000,000, £6,000,000,000,000,000,000, £7,000,000,000,000,000,000, £8,000,000,000,000,000,000, £9,000,000,000,000,000,000, £10,000,000,000,000,000,000, £15,000,000,000,000,000,000, £20,000,000,000,000,000,000, £25,000,000,000,000,000,000, £30,000,000,000,000,000,000, £40,000,000,000,000,000,000, £50,000,000,000,000,000,000, £60,000,000,000,000,000,000, £70,000,000,000,000,000,000, £80,000,000,000,000,000,000, £90,000,000,000,000,000,000, £100,000,000,000,000,000,000, £150,000,000,000,000,000,000, £200,000,000,000,000,000,000, £250,000,000,000,000,000,000, £300,000,000,000,000,000,000, £400,000,000,000,000,000,000, £500,000,000,000,000,000,000, £600,000,000,000,000,000,000, £700,000,000,000,000,000,000, £800,000,000,000,000,000,000, £900,000,000,000,000,000,000, £1,000,000,000,000,000,000,000, £1,500,000,000,000,000,000,000, £2,000,000,000,000,000,000,000, £2,500,000,000,000,000,000,000, £3,000,000,000,000,000,000,000, £4,000,000,000,000,000,000,000, £5,000,000,000,000,000,000,000, £6,000,000,000,000,000,000,000, £7,000,000,000,000,000,000,000, £8,000,000,000,000,000,000,000, £9,000,000,000,000,000,000,000, £10,000,000,000,000,000,000,000, £15,000,000,0

Surgeon Commander Alice Reddingfild Marsh, R.N., died at Harast on September 11th, aged 56. He was the son of the late Henry Marsh, polymatier-in-chief. R.N., and was educated at Edinburgh University, where he graduated B.Sc. in 1899, and later serving as assistant medical officer of the county asylum at Warrwick. He entered the Navy in 1904, and became a Surgeon Commander in 1917. He served along with the Prince of Wales on H.M.S. "Heron" and at the beginning of the late war was a shipmate of H.M.R. Duke of York on H.M.S. "Colingwood". After he was on board H.M.S. "Dorsetmouth" when she was torpedoed in April, 1916, and afterwards served in the Royal Naval Air Wing at Germany. For the past two years he had filled the post of Senior nurse, and thorax specialist at the Royal Naval Hospital, Haslar. He made the observation that that poison gas can produce fatal effects by entry through the ear, and invented an extension of the gas-mask to prevent such entrance. He acquired lung disease through exposure during the evacuation of Russian refugees in the Black Sea in 1919. He leaves a widow and two children.

The Prince of Wales, who is Chancellor of the University of Wales, has promised to visit the University College of Wales at Aberystwyth on October 30th, when he will open

A William Farr lecture, on the measurement of progress in public health, will be given by Sir Arthur Newsholme, London School of Economics and Political Science (Houghton Street, Aldwych, W.C.2). The lecture is open to the public.

The opening meeting of the North-East London Clinical Society will be held on Thursday, October 4th, at 4.15 p.m., when Dr. C. F. Still will give a lecture on common errors of diagnosis in diseases of children. The president, Dr. A. J. Warington, will be in the chair. The annual dinner of the Society will take place at the Prince of Wales's Hospital, Tottenham, on October 11th, at 8 p.m. Dr. A. J. Warington M.C.E. Scott has been presented by the Women's Guild of the Parish Church, Laurencekirk, with a writing case and a wallet of Treasury notes on the occasion of her departure for T'chang, China, where she will take up duty in the Buchanan Memorial Hospital. The annual dinner of past and present students of University College Hospital will be held on Friday, October 5th, at the Hotel Cecil, Strand. Tickets (price 15s. 6d.) can be obtained from Mr. Gwynne Williams and Dr. T. R. Elliott at 24, Bedford Square, W.C.1.

The annual dinner of the Cambridge Medical Society will be held in the hall of King's College, Cambridge, by kind permission of the Provost and Fellows on Saturday, September 23rd, 1925, at 7.30 for 7.45. Tickets, price 15s. inclusive of wine, should be obtained before September 21st from Dr. G. S. Haynes, 58, Lensfield Road, Cambridge. A meeting of the society will be held at Addenbrooke's Hospital on Friday, October 5th, at 2.30 p.m. By arrangement, all members of the Cambridge and Huntingdon Branch of the British Medical Association are entitled to attend the meetings of the society, which are held monthly, except during August and September, and count as clinical meetings of the Association. The annual dinner of the West Kent Medical-Chirurgical Society will be held at the Trocadero Restaurant, Piccadilly, Circus, London, W.1, at 7 for 7.30 p.m. on Thursday, October 4th. Applications for tickets should be addressed to Dr. C. J. D. Buchanan (Hon. Sec.), 326, Brownhill Road, London, E.5.

Dr. STEPHAN VON ARTIMY, professor of zoology at the University of Kolosvary, who was well known for investigations on neuro-histology, recently died at the age of 69. The Society of Public Analysts will resume its monthly meetings on October 3rd. The society meets in the rooms of

The Advisory Committee on Industrial Hygiene, which has just ended its sittings at the International Labour Office of the League of Nations at Geneva, adopted a resolution stating that the most effective method of securing the success of research into the prevention of such work would be the constitution of national committees to work under the general direction of the Health Committee of the League of Nations. Members might with advantage be appointed also in connection between the Health Committee of the League of Nations and the Government departments in each country which are responsible for the administration of the Factory Acts. Dr. Remy, assistant professor of industrial hygiene at Pennsylvania University, described his method of iodine disinfection to the committee, which expressed the hope that his observations would be followed up. The committee also discussed

The tenth Norman Kerr memorial lecture of the Society for the Study of Inebriety will be delivered by Sir William Whiteley, K.C.I.E., M.D., at the house of the Medical Society of London (11, Chandos Street, Cavendish Square, W.), on Tuesday, October 9th, at 4 p.m. The subject chosen is

Dr. C. E. Lay of Peasbuhl has, on the occasion of his remaining after forty-two years' practice in the district, been presented by the parishioners of Badlingham, Bransgarp, Haveringbham, Huntingfield, Peasbuhl, and Sibton, with a

The National Hospital for the Paralyzed and Epileptic has issued a syllabus of a post-graduate course to begin on October 8th and to continue until November 30th. After noon, each day will be pretty fully occupied by lectures and demonstrations on the pathology of the nervous system, by attendance at out-patient clinics, and by clinical lectures and demonstrations. Members attending the course will be entitled to witness operations. The inclusive fee will be £100 guineas, but any part of the course may be taken separately. Full particulars can be obtained from Dr. C. M. Hines, dean of the Medical School, at the hospital (Queens

The report for 1922-23 of the Professional Classes Aid Council, upon which the British Medical Association is represented by Dr. G. E. Haddy, shows that useful work continues to be done by this organization, which exists in order to assist in relieving distress among the professional and educated classes and their dependants. It does more than merely make grants of money, its aim being to enable the recipient of assistance to become independent of further help. During the year the council dealt with 532 new applicants of whom 271 were, however, not within the scope of the organization and 22 were otherwise unsatisfactory.

The Institute, Dr. W. R. Collier or Mr. Hugh Whitehead, at  
secretaries, Dr. W. R. Collier or Mr. Hugh Whitehead, at  
pated and will be talking from either of the honorary  
and with the room. A detailed programme is being pre-  
paring and two sessions of one and a half hours  
to 600. There will be clinics and demonstrations  
the Redcliffe Institute, Oxford: it will last from October  
A post-graduate course will be held as usual this year at  
Square, Bloomsbury, W.C.1.

and 89 old applicants (of whom 33 had recently to be retrained). In addition, 50 trainees received assistance in providing education. The expenditure for the year amounted to £2,347, showing a deficit of £2,113, and an appeal is therefore made for increased financial support. The officers of the council are at 251, Bromley Road, Gypsy.

THE London School of Tropical Medicine has arranged to send a number of students to Canada to study the prevention of malaria in the States which attract a large proportion of immigrants.

The Home Secretary has made a Regulation, dated September 10th, empowering port medical officers to issue certificates to masters of foreign ships authorizing them to obtain, within certain limits, dispensations containing opium, cocaine, morphine or heroin which are required to complete the necessary medical equipment of the ship. These certificates when presented are to be treated by the supplying chemist in a similar way to prescriptions given by a doctor to a patient.

er, and the Government of New Zealand will have its headquarters at Apia and will be away for two years; it will work in co-operation with the New Zealand Government, which is responsible for the administration of Samoa. The expedition, which will leave this country on November 15th, will be under the leadership of Dr. Patrick Buxton, who did valuable work on entomology in Mongolia during the war, and has recently been entomologist to the Rastine Government at Jerusalem.

## PSEUDO-CYESIS.

The following notes on a case of pseudo-cyesis, which came under my notice some time ago, appear to be sufficiently interesting to be recorded. I have altered the dates throughout, for obvious reasons.

In the middle of June, a woman, aged 46, who had had several children but had been a widow many years until she remarried late in the preceding year, consulted me about her condition as she thought she was pregnant again. I ascertained that the menstrual periods were quite regular and found no signs of pregnancy, and informed her that she was mistaken, and to convince her pointed out that there was no enlargement of her breasts and that they contained no secretion as they had no doubt done in her previous pregnancies.

She went away convinced of her mistake, as I thought, but returned in September and informed me that I must have been mistaken about her condition as she was sure she was pregnant, and that now her breasts had enlarged and contained milk. This, to my surprise, proved correct, but she was not pregnant, and she denied having stimulated the breasts in any manner. I again assured her that she was not pregnant. She returned, however, early in the following November to ask when the baby would be born. Examination then showed a copious secretion in both breasts. After further assurance she went away, and although I saw her several times afterwards the subject was not mentioned again.

D. S. PRACY, F.R.C.S. Edin.

## VOLVULUS OF AN ASCENDING COLON.

Mrs. —, aged 69, who had been delicate as a girl, spending eight winters on the Riviera, and in whom shocks such as bad news usually caused vomiting, had, when I saw her, for one month experienced some abdominal discomfort, but "nothing to speak of."

Abdominal pain and vomiting commenced on April 29th, 1923, and continued during the night. When seen next day the abdomen presented a smooth elastic swelling about the size of a full-time foetal head, above and to the left of the umbilicus; it was movable, resonant, fluctuant, with no fluid thrill and no pelvic attachments. The next day she was comfortable, but after visiting her physician and dining, vomiting recommenced. She was not seen for forty-eight hours, when it was evident that an acute condition existed in the abdomen.

I made a median incision from the xiphisternum to below the umbilicus; at first sight the rounded swelling appeared to be a distended stomach, but the hand moved freely round and the appendix presented on the top of it. It was easily delivered; the ileum was above and in front of the liver and stomach, and wound round the hepatic flexure clockwise. After unwinding and replacing the small bowel the transverse colon was demonstrated; the hepatic flexure was thoroughly freed from adhesions, the transverse colon inflated well, and the caecum and ascending colon were replaced; breathing being difficult, further operative procedure was contraindicated.

With the exception of difficult deflation she made an uninterrupted recovery.

Guildford.

A. H. BRODRIBB.

## WANDERING SPLEEN IMPACTED IN THE PELVIS.

The following case appears worthy of record, as without laparotomy a true diagnosis could not possibly have been arrived at.

A Mohammedan woman, aged 28, was admitted to hospital on May 31st, complaining of a tumour in the abdomen which caused pain. She gave its duration as two years, stated that her periods had been regular during this time, but that she had had frequent attacks of malaria. The history in such cases is as a rule unreliable, since patients' ideas of time are vague, and they have an impression that the longer they state they have suffered from a disease the

more attention will be paid to their case. In this case, on examination, a centrally situated, hard, irregularly nodular tumour was found rising to within an inch of the umbilicus. A provisional diagnosis of fibroids was made. On examination per vaginam, a hard tumour was found occupying the whole of the true pelvis. Attempts to pass a sound failed on two occasions, and it was thought one had to deal with a cervical myoma. The woman was kept under observation for five days, during which time she had evening rises of temperature to 100° F. or so, on alternate days, and she was given quinine.

Preparations having been made for dealing with a difficult hysterectomy I opened the abdomen on June 5th. Exposure of the upper end at once revealed the nature of the tumour, as splenic tissue was recognized. The incision was enlarged downwards, the absence of adhesions verified, and the tumour easily brought out of the abdomen. The pedicle being long its ligature and division was a simple matter. The condition of the other pelvic organs was then looked into. The uterus was found flattened out against the rectum, and had the appearance of a broad thick ribbon; hence my inability to pass a sound. The patient made an uneventful recovery and was discharged cured (*minus* her spleen) on June 21st, sixteen days after operation.

The pathological report by Lieut.-Colonel F. P. Mackie, I.M.S., states as follows:

"The tumour in the spleen was originally of a cystic nature, evidence of loculi still remaining. At some time suppuration must have taken place and probably some haemorrhage. The structure is now that of dense sclerosing connective tissue, laminated at the peritoneal edge and more open in the interior. No signs of pus are now present, nor were micro-organisms seen. There is no evidence of hydatid membrane."

A. J. VERNON BETTS, M.B.Lond.,

Civil Hospital, Nasik, India.

Lieut.-Colonel I.M.S.

## Reports of Societies.

## REST IN THE TREATMENT OF PHTHISIS.

At a meeting of the Brighton and Sussex Medico-Chirurgical Society, held on September 6th, with the President, Dr. ELIOT CURWEN in the chair, Dr. A. NEVILLE COX read a paper on local and general rest in the treatment of phthisis. He referred to the effects of overfatigue in industry, and its share in causing the breakdown in cases of phthisis. The betterment of industrial conditions, especially in shortening the hours of work, brought about by the Factory Acts and otherwise, must have played an important part in the reduction of phthisis mortality among women. Up to 1866 the female death rate was higher than the male, but since that time the female rate had always been lower, and was falling more rapidly. In Dr. Cox's opinion the increased mortality among women during the war was due largely to physical overstrain in the munition factories, combined with poorer feeding. Where fatigue had been the chief cause of a disease, rest must be the chief measure in its treatment. The literature of tuberculosis showed remarkable changes of opinion on the relative merits of rest and exercise in the treatment of phthisis. Even now there was one school, especially in America, which advocated rest and another which relied rather on exercise; in this country the tendency was to underrate the importance of rest. The indications for rest were the toxæmic symptoms. Dr. Cox described the methods of securing general rest for the body in the several stages of the disease, and in particular the details of "absolute rest" as laid down by Paterson. He pointed out that the phthisis patient, even when his disease was becoming quiescent, should do everything "on low gear," and should stop short of fatigue in his exertions; hence the great difficulty for exsanatorium patients in competing with healthy men at their old occupations. The success of pneumothorax treatment and of the conservative treatment of surgical tuberculosis had led to renewed interest in the possibility of obtaining local rest for the affected lung. The natural means by which the body endeavoured to limit function in the diseased lung were outlined; and several ways in which this process might be helped, by posture, control of breathing, and various forms of lung-splints, were described.

## Medicine.

recorded two cases in which syphilitic infection appears to be proved. Carnot and Harey have recorded a still more typical case. The authors state that syphilitic pancreatic diabetes does occur, but that it would appear to be extremely rare. An isolated gumma is insufficient to produce diabetes, but a generalized sclerositis may do so. In hereditary syphilitic diabetes lesions associated with diabetes appear to be much more common; several cases are quoted. Syphilitic lesions of the liver are much less definitely associated with diabetes, which is still more rarely found in cases of cerebral syphilis. After discussing many other recorded cases of syphilitic lesions in other organs in diabetic patients the authors conclude that in the vast majority of cases syphilis plays no part in the production of diabetes; statistics show that syphilis is not more frequent among diabetics than among other patients, and that diabetes cannot be shown to occur with special frequency among syphilitics. Clinical experience shows that specific treatment in these cases is usually ineffectual. The similarity of diabetic and syphilitic nerve lesions is a fallacious argument. Congestive diabetes may be due to common hygienic errors. However, certain cases of syphilitic diabetes do exist, produced by syphilitic lesions of the pancreas, liver, nervous system, and possibly of the hematopoietic system; such cases are very rare but most interesting because of the curative action of specific treatment in many of them.

## Toxic Effects of Digitalis.

210. Endemic Malaria in Germany.  
A. ROSENBERG (*Deut. med. Woch., June 22nd, 1923, p. 811*) draws attention to the alarming increase of cases of malaria occurring in persons who have never lived outside Germany.

ndemic malaria in Germany.

210. **Endemic Malaria in Germany.**  
A. ROSENKRANZ (*Deut. med. Woch.*, June 22nd, 1923, p. 811) draws attention to the alarming increase of cases of malaria occurring in persons who have never lived outside Germany. A collection of the records of such cases shows that among thirty-eight patients there were only two women. This difference in the sex incidence can probably be traced to the fact that women work out of doors much less than men, and are therefore less exposed to infection by mosquitoes. Of all the cases of malaria recently observed in Germany 57 per cent. represented endemic infection, the patients concerned never having left Germany. About 50 per cent. of the cases of tropical malaria also belonged to this category. A point to which the author attaches great importance is the tendency which the records show when endemic tropical malaria occurs, and to trace the symptoms to some acute abdominal condition. This mistake is the more likely as the symptoms in tropical malaria may be very variable, and the author recorded two cases in which tropical malaria was regarded as at first. In one case peritonitis was diagnosed and looked at as such. In the other case perforation of a gastric ulcer was diagnosed, and the patient sent to a laparotomy performed. In both cases the temperature curve was not characteristic, and in both cases the clinical picture was dominated by signs of abdominal disease. The lesson to be drawn is that a blood examination in cases of malaria parasites may give useful information in cases which might otherwise suffer severely at the hands of the laparotomizing surgeon.

208. The Place of Syphilis in the Etiology of Diabetes.

in great detail, and anyone interested in a particular subject will find a wealth of information. We may refer to some points of special interest: it is stated that the harmful effect of exposure is to some extent counteracted by a liberal ration and daily hot food. Men in the trenches were given daily an extra three-quarters of an ounce of sugar. It was found in Gallipoli, where cases of beriberi occurred, that yeast was the most efficient prophylactic. A table is given showing the antiscorbutic and antiberiberi value of various foods. Besides the usual analyses of water, food, and drugs, and toxicological work, the base hygiene laboratory was called upon in 1918 to make the gum fluid to be used for saline infusion; it contained 6 per cent. of gum in a 0.9 per cent. solution of sodium chloride; as much as 75 litres was made daily and sent up the line.

In Eastern Europe malaria occurred mainly, as was to be expected, along the courses of rivers and in wide valleys with swampy borders. One of the deciding factors was the temperature; the disease occurred as high as 4,000 feet, but there was none at Monastir, at an elevation of 2,000 feet. In Egypt and adjacent countries malaria did not occur on desert land, but oases and irrigated areas were associated with virulent malaria; the commonest type of malaria was benign tertian, and the next malignant malaria, either alone or in conjunction with the former. Quartan was the least common. It is remarked that mass-debility from malaria far exceeded the losses from any other disease. The measures taken to combat the disease can be classified as (1) drug prophylaxis, (2) culicifuges, (3) personal protection, (4) mosquito destruction. Quinine was extensively used as a prophylactic, but no clear opinion of its value was reached. The method of administration varied greatly, and we advise the reader, in order to obtain a wider view on this point, and more detailed information, to refer to the articles on the subject in volume I of the *Medical Diseases of the War*. Cerebro-spinal fever broke out in military camps in England early in 1915 under conditions of overcrowding, and the investigations and preventive work carried out by specially appointed officers are described in great detail.

The methods of dealing with flies and lice are discussed in separate chapters. The relation of fly prevalence to dysentery is indicated, as is also the importance of manure as a breeding ground; full particulars are given as to the method of rendering manure heaps harmless. It was always found that where burial of refuse took the place of incineration flies at once became prevalent. As regards lice, which are the means of conveyance of typhus, relapsing fever, and trench fever, the complete dependence of the louse on man's blood is emphasized. The steps taken to detect its presence and to carry out cleansing of the men and disinfection of clothing, bedding, and billets are described. All eggs are killed by exposure to 2 per cent. lysol for five minutes at a temperature of 50° to 65° F., and to 2 per cent. lysol or cresol in twenty minutes at room temperature. The various pieces of apparatus used in disinfection by heat are described. Sir W. HORSBOKS concludes that it is probable that in the war 50 per cent. of the admissions to hospital from troops in the field armies were attributable to lack of personal cleanliness and to vermin. The importance therefore of every possible facility being provided for men to keep themselves, their clothing, bedding, and billets, free from vermin cannot be over-emphasized. As regards scabies, it was found that the best ointment was sulphur of a strength of 1 in 15, the B.P. strength of 1 in 10 being too irritating. An interesting chapter deals with the subject of trachoma, which occurred mainly in the native labour corps.

With regard to small-pox, the lesson taught by the war is that where compulsory vaccination is not allowed, and unprotected men are sent to a war area where small-pox is endemic, a sharp epidemic may flare up.

#### A VIENNESE TEXTBOOK OF FORENSIC MEDICINE.

WHEN in 1878 Hofmann published his textbook on forensic medicine the work was recognized as initiating a new era in regard to the subject. By his investigations and experimental inquiries into the changes which occur in the body after death, into violent asphyxia, especially drowning, and into the effects of various forms of violence, he showed the

inaccuracy of many accepted views and placed the whole subject upon a more scientific basis.

His textbook is classical and served to attract to Vienna and to inspire a large number of pupils who have become distinguished in this branch of medicine. The book rapidly passed through eight editions under his supervision, Kolisko edited the ninth, and now we have the tenth edition, which has been completely revised and brought up to date by Professor HABERDA, his successor in the chair at Vienna and an outstanding authority on all medico-legal questions.<sup>2</sup> No man was more fitted for the task, from his distinction as a writer and investigator and also from his having had at his disposal for nearly thirty years the immense material of the Medico-Legal Institute at Vienna.

The new edition is considerably enlarged and has now over 200 illustrations. It contains an account of recent advances, written so as to afford medical men all that is essential and yet without overstepping the limits which must control a general textbook. Copious references to recent literature enhance the value of the work for those engaged in more advanced study, while the section of medico-legal psychiatry has been ably rewritten by Professor Wagner Jauregg.

It is no exaggeration to say that it is the best and most complete textbook on the subject in any language.

#### THE THERAPEUTICS OF DIGITALIS.

THE monograph on *The Therapeutic Use of Digitalis*<sup>3</sup> by G. CANBY ROBINSON, Professor of Medicine at the Vanderbilt University, is a reprint of the article which appeared in the first number of *Medicine*, a quarterly review of medicine, neurology, and pediatrics, published in May, 1922. Professor Robinson presents us with a critical review of the very extensive literature on the subject of digitalis, but with the ultimate object of sifting out from the results that have been obtained by observation and experiment what is of practical application and suited to the needs of practitioners of medicine. The various members of the digitalis group are considered and the different methods of determining the potency are discussed. The author favours the "cat" method of assay, and he gives a table showing the relative potency of some of the preparations of digitalis and its allies, in terms of the amount of the drug in milligrams which is the fatal dose for the cat on the basis of 1 kilogram of body weight—that is, which is equivalent to 1 cat unit. He makes a strong plea for the standardization of the drug on this basis. In the case of the tincture 1 c.cm. should represent 1 cat unit. The toxic effects of the drug on the gastro-intestinal tract or on the heart are dealt with in much detail in view of the importance of their early recognition in carrying out efficient treatment. The effects of therapeutic doses of the drug on heart muscle, on the cardio-inhibitory mechanism, on the blood vessels, and on the kidneys are then discussed and the practical application of the whole is reached in chapters which treat of the use of the drug in heart failure. This part of the book is expanded and the various disorders of cardiac mechanism, valvular disease, muscle incapacity, or nerve disturbance are treated separately.

In discussing dosage and method of administration the "Eggleston" method receives attention. As a result of experiment it has been found that 0.15 cat unit per pound of body weight is likely to give the maximum therapeutic result. As most high grade tinctures have a strength of about 1 cat unit per 1 c.cm., it is possible to calculate the amount of tincture likely to be required in any case—for example, a patient weighing 140 lb. would require about 21 c.cm., and this could be administered in a few doses, beginning with, perhaps, half the total quantity and giving the remainder in diminishing doses.

There are 163 references to the literature of the subject from American, British and other European publications. The book will be found of value to any who are interested in cardiac problems.

<sup>2</sup> *Hofmann's Lehrbuch der Gerichtlichen Medizin*. Edited by Professor Albin Haberdar. Tenth edition. Vienna: Urban und Schwarzenberg. 1923.

<sup>3</sup> *The Therapeutic Use of Digitalis*. By G. Canby Robinson. *Medicine* Monographs. Vol. I. Baltimore: Williams and Wilkins Company. 1923. (Med. 8vo, pp. 137. U.S., Canada, Mexico, Cuba, 2.50 dollars; other countries 2.55 dollars.)

that in the yellow and negro races this congenital dislocation is much more rare than in the white races, and he associates this rarity with the less highly developed brain of the negro and the yellow man. No reference is made to the indisputable fact that the pelvis of the anthropoid apes is far more capacious than that of man, a fact which entirely upsets his theory that pelvic development necessarily depends on the size of the foetal skull.

Dr. P. Le Damany makes the surprising statement that in some parts of Brittany, in which province he practises, there is one case of hip luxation to every sixty or seventy inhabitants and that its frequency constitutes a real public calamity. He does not drive his argument home by insisting that this frequency is due to an overwhelming intellectual superiority of the Breton Celt over the Teuton and the despised Sassenach. In this country there has been no census of cripples and therefore exact comparisons are impossible, but it is obvious from the statistics of our hospitals that the frequency of the deformity here cannot be a tithe of that in Southern Brittany, for it occurred in less than 1 per cent. of 5,000 orthopaedic cases. In Germany, according to Hoffa writing in 1891, there were only seven congenital hip dislocations in 10,000 surgical cases. The very fact of the extreme regional variability of the frequency of the deformity recorded by the author surely shows that some factor other than mental development has a preponderating influence on its incidence.

Dr. Le Damany also claims to have accounted for torsion of the upper end of the femur, which he regards as a cause and not as a consequence of its displacement, but we are not convinced by his argument; in fact we cannot admit his premisses.

The vast field of experience which Brittany has apparently afforded to the author makes us turn with great expectation to the section of the book on treatment. In this we are not disappointed, although it contains little that is new, except the description of the author's method of treatment after the first plaster appliance is removed. He advocates a combination of plaster-of-Paris and steel apparatus, designed to allow of limited movement, with the intention of encouraging joint development by use. It may be doubted whether the same end is not attained by the ordinary plaster appliance, which generally allows of movement to a greater or less extent. We should have liked to know what degree of success Dr. Le Damany has had, but beyond stating that in very young children (presumably under 2 years of age) 95 per cent. may be counted as cured, he modestly refrains from making any categorical claims to success. We believe that in this country most orthopaedic surgeons consider that the difficulties of treating very young children outweigh the advantages to be hoped for from early attempts at reduction dislocation.

Though we cannot accept all Dr. Le Damany's conclusions we must pay full tribute to his research and industry and to the ingenuity with which he has attempted to explain the etiology of a deformity, which still continues to baffle the pathologist.

The publishers state that this series is intended for the instruction of the general public, and that this book will interest the 120,000 French people who are the subjects of congenital hip-luxation, but we judge it to be too technical for a popular work.

### NOTES ON BOOKS.

A HANDY pocket book on *Hygiene and Disease in Eastern Tropical Africa*,<sup>1</sup> prepared on behalf of the Admiralty and the War Office, has been issued by H.M. Stationery Office as a supplement to the *Handbook of German East Africa*. The compiler, who is anonymous, writes after an experience of two periods of about three years each in eastern tropical Africa in the midst of many of the diseases which he discusses, and had no illness of any account owing to the observance of the simple rules which he lays down for steering clear of disease. He has succeeded in producing a little volume that is admirably clear and intelligible. It is well illustrated and has an excellent map of German East

Africa showing the distribution of the tsetse fly. It should prove an invaluable companion and guide to all who intend to travel or settle in East Africa, or indeed in any country where tropical diseases occur. Not the least of its merits are its conciseness without loss of any essential matter or of lucidity and the convenient pocket size of the volume. A short section on the protection of aircraft from the attacks of insects gives an account of the insects, such as the wood-boring beetles, which attack woodwork, and the white ants, which are a much more serious danger, as they can summon large numbers to the attack whenever they find a substance suitable for food, thus effecting an astonishing amount of damage in a single night, as those who have lived in India and the tropics know only too well. The most effective means of protecting the structure of aeroplanes from these pests are well described. The Admiralty and the War Office are to be congratulated on the issue of this extremely useful little volume. It is quite the best of its kind.

The possibility of producing adequate supplies of quinine within the empire is discussed in a report<sup>2</sup> issued a short time ago by the Imperial Institute. The extent to which this country depends for its supply on foreign sources is pointed out and a policy of aid by the Imperial and Indian Governments for the more extensive cultivation of cinchona bark suggested. The report also deals with tanning materials in the same way, giving statistics of the trade in Indian myrobalans and indicating the lines on which the production and trade could be improved.

The appearance of a third edition of Professor DENDY'S *Outlines of Evolutionary Biology*<sup>3</sup> calls for no long comment. The book has such a wide reputation, and has met with such a universally favourable impression, that there is little more to be said. It will be a matter for surprise if many more new editions are not called for. The present edition has been revised and brought up to date; as shown, for example, by the inclusion of the experiments of Guyer and Smith and of Cunningham's hormone theory in the chapter dealing with the question of the inheritance of acquired characters—a question of the most vital importance in all matters relating to medicine and sociology. The book deals largely with debatable matter, but the various views are set forth in an unbiased and truly scientific spirit. One point worthy of special mention is the completeness and accuracy of the index, which enhances the value of the book. Index compiling is a dreary occupation and in a book of this character with so many cross-references a very difficult one, but the result is excellent. Professor Dendy is to be congratulated very sincerely on the appearance of this edition. Like its predecessors it is admirably written, filled with information well presented and extremely interesting; what more can be desired?

We have received from the publishers a copy of a new professional directory entitled *London Doctors and Dental Surgeons, 1923-1924*.<sup>4</sup> The first part gives a list of registered medical practitioners practising in Greater London, including Beckenham, Bromley, Croydon, Ilford, Kingston, Richmond, Surbiton, and Woodford. The second part gives a list of "legally qualified (registered) graduates and licentiates in dental surgery" practising in the same area. In size and shape of page, in style and size of type, in tabular arrangement of the entries, as well as in colour and style of binding, this directory bears the strongest possible resemblance to the *Medical Register*; in bulk it corresponds more nearly with the *Dentists Register*. The preface states that no name is printed which for any reason does not appear in the *Medical* or *Dentists Register*, as corrected up to May 31st, 1923, by the General Medical Council or the Dental Board. The brief information appended to each name is arranged in vertical columns. In the medical section each page has five columns, and in the dental section four. The names of dental surgeons who are also registered medical practitioners appear in both sections. The personal particulars given are stated to be those furnished by the practitioners themselves; but "where no return was received, or information was forthcoming too late for incorporation in the present edition, the matter actually appearing is taken from the *Medical* and *Dentists Registers*, amplified wherever possible by available official data."

SATURDAY, SEPTEMBER 22ND, 1923.

## THE HEALTH OF SCOTLAND.

ELSEWHERE in this issue (p. 540) are given some striking statistics drawn from the report for 1922 of Dr. A. K. Chalmers, M.O.H. Glasgow. They relate not merely to the great city on the Clyde, but to Scotland as contrasted with England and Wales. Taking first the cities of the two countries, the mean of the all-age death rates of the three years 1920-21-22, in London was 12.8 per 1,000 living, in Liverpool 15.0, in Manchester 13.8, and in Birmingham 12.0. In Scotland the comparable figures were—Edinburgh 14.3, Aberdeen 15.1, Dundee 15.4, and Glasgow 15.9. Next, comparing England and Wales as a whole with Scotland as a whole, the death rate of Scotland since 1861 has been higher by either 1 or 2 per 1,000 per annum in every decennium excepting 1881-90, when the rates were equal. The facts as to infant mortality are even more arresting. In 1861-70 there were in England 154 deaths per 1,000 births, and in Scotland only 121, a difference of 33 in favour of Scotland. But after that time the difference so diminished that in 1901-10 Scotland had an advantage of only 14 instead of 33. In 1911-20, for the first time in those sixty years, the rate in England was lower than in Scotland by 6 per 1,000. It is not that Scotland has been standing still. In 1891-1900 its figure was 128, and in 1911-20 it was only 106; but in England, whilst the rate was 153 for 1891-1900, it had fallen to 100 for 1911-20.

These comparisons, so disadvantageous to Scotland, suggest serious questionings. Why is it that the mortality of Scotland for all ages is persistently higher than that of England? An excess of even 1 per 1,000 per annum means close on 5,000 extra deaths every year. Comparing Glasgow, which has the highest death rate of the four great towns of Scotland, with the four greatest English cities, and confining the comparison to 1921, the healthiest of the past three years, the position is as follows. Glasgow had 16,051 deaths; if it had had the same death rate as Liverpool (14.3) its deaths would have been 15,200, a saving of 851 lives. If it had had the same death rate as Manchester (13.6) it would have had 14,456 deaths, a saving of 1,595 lives. If it had had the same death rate as London (12.4) its deaths would have been 13,171, a saving of 2,880 lives. If it had had the same death rate as Birmingham (11.2) its deaths would have been 11,243, a saving of 4,808 lives.

Our purpose is to ask questions, not to answer them; but as the four great towns of Scotland include about three-eighths of its total population, and as combined they have a very decidedly higher death rate than the four greatest towns of England, they must largely account for the national difference.

We pass on, however, to suggest matters for consideration as to the high urban death rates of the northern kingdom. Housing at once suggests itself, and there can be no doubt of its immense influence. In his admirable health history of Manchester noticed

in last week's issue (p. 468), Dr. Niven describes it as a city of cottage dwellings, the prevailing type being the four-, five-, or six-roomed house. How infinitely better this is than the great four-story buildings of Glasgow, with multiple houses on every floor, packed full of humanity in dwellings mostly of two apartments, but not infrequently of one; all reached by a common stairway which conveys not only human traffic, but some share of every kind of atmospheric pollution resulting from the overcrowding. This is no modern phenomenon; it is the growth of centuries. The reason probably is that Scotland was in past times a poor country, whose inhabitants could not afford such houses as were practicable in the South, so that a custom became established of a Scotsman having a smaller dwelling than an Englishman. At the best improvement here can only be gradual. It would take an earthquake to effect a clearance. Nor will the housing habit be broken by the bellows of the Clydeside no-renters, who do so much towards preventing unaided private enterprise from resuming its building function. Neither local authorities nor central authority are too much to be blamed for evils which have their roots deep in the past, and health reports such as that of Dr. Chalmers show how strenuously evils are being tackled in the present day.

Closely associated with overcrowding is the question of domestic cleanliness with all its obvious relations to health, and especially to the health of infants and children. Is the standard of cleanliness lower in Scotland than in England? Does milk, for example, keep as well in a two-roomed dwelling in a great tenement building in Bridgeton as in a separate house in a street in industrial Old Trafford? If not, is the difference wholly due to the house, or partly to the housekeeper? Can school medical inspectors and health visitors make any comparison here between England and Scotland in respect, say, of cleanliness of skin and hair and clothing and of the dwelling itself? If there is a difference no doubt it is being much diminished by such agencies.

A third question—and it cannot be shirked—is the comparative prevalence of alcoholism in the two countries. The spectacle presented by Argyll Street and Trongate in Glasgow on a Saturday night has often been commented on by visitors, and no doubt also by residents, though these may be compelled to silence by shame. Is that to remain a permanent disgrace, or will the coming vote under the Temperance Act do something to diminish it? The influence of alcoholism on the life and health of the victims themselves, and almost as directly on the life and health of their offspring, and on housing and domestic comfort, indeed on all the problems of sociology, needs no emphasizing.

These three subjects—housing, cleanliness, and alcoholism—are closely intertwined. Better houses would promote cleanliness and temperance; greater domestic cleanliness and comfort would provide a counter-attraction to the drink shop; less money spent on drink would leave more for house rent and food and clothing; parental sobriety would mean a cleaner house and better cared-for children. It does not matter where the cutting of the vicious circle begins; improvement in one direction will mean improvement in all.

A fourth question is as to atmospheric pollution in the cities of Scotland and of England. The average Scottish coal is dirtier than the average English and Welsh coal. The pall of smoke overhanging great cities is seen by every railway traveller as he

signs—then there remain 150 colonic to 50 ileal obstructions; that is, there is slightly greater than a 2 to 1 chance of any acute intestinal obstruction being situated in some part of the colon. A careful inquiry into the previous medical history is helpful, the entire absence of any intestinal troubles prior to the onset of obstruction being in favour of the small intestine; of all causes of acute colonic obstruction 87 per cent. are due to malignant growths, and this usually produces some previous intestinal disturbances, such as colicky pains after meals, often travelling to and becoming arrested at the same spot, associated with boring or diarrhoea (especially when the right half of the colon is concerned), gradually increasing constipation in growths of the left side, slight attacks of intermittent distension often alternating with diarrhoea, occasional passage of blood-stained. In less acute types the assistance of the sigmoidoscope and of radiography after a barium enemata may be sought, but there are scarcely practical in the really acute case. It is mainly upon a physical examination of the distended abdomen that one has to rely for differential diagnosis: its shape, whether the bulging is confined to the flanks as in large gut obstruction and especially when the ileo-caecal valve is competent, or whether it is mainly the central parts that are distended as in obstruction in the small intestine; whether the outlines of individual distended coils can be seen forming "ladder patterns" as in ileal obstruction; whether the peristaltic wave passes along it—"palpable peristalsis," auscultation—a much neglected method of physical examination of the abdomen—is often extremely useful if one is conversant with the character and site of the normal intestinal sounds and of the alterations in tone, intensity, and distribution met with in obstructive conditions. "Key-note," to the diagnosis is, failing this, if it can be definitely felt to alternately harden and soften under the examining fingers, upon the obstruction is distal to it. It is unnecessary to do the extreme importance of a careful rectal and vaginal examination.

If, however, a painstaking investigation on these lines fails to show whether the obstruction is in the small or the large intestine, then the first step in the operative treatment must, except in the most desperate cases, necessarily be in the nature of an exploratory laparotomy. This I believe to be best carried out through a paramedian incision splitting the fibres of the portion of the right rectus abdominis, and just large enough to admit the hand, every care being taken to the escape of distended bowel. The caecum is at once felt for, and in cases of colonic obstruction will be found distended. The sigmoid colon is next examined, and if found distended the condition is a volvulus (suspended) or extreme, or an obstruction in the lower sigmoid or rectum, which palpation is next drawn down and the transverse colon examined; if this is distended the hand is passed in a distal direction, palpating the left half of the transverse colon, the splenic flexure, and descending colon until the obstruction is felt; if collapsed, a similar investigation is made of the right half of the transverse colon, hepatic flexure, and ascending colon. If the condition of the patient be grave this examination of the sigmoid and transverse colon must be omitted, and once it has been decided that the caecum is distended, the incision should be rapidly closed and caecostomy performed through a "gridiron" incision in the right iliac fossa, a small Paul's tube being fitted into the caecum, or a rubber tube introduced similarly to that in the Kader-Senn operation of gastrostomy, or by the method described by Lockhart-Mummery in the *Lancet* of November 25th, 1922. In a few cases I have introduced the tube through the appendix (appendicostomy), but it is exceptional thus to be able to introduce a tube sufficiently large to give material relief.

When the site of the obstruction in the colon has been located and the cause is found, as is most frequently, to be a growth, then its local fixity, the extent of glandular involvement, and the presence of secondary deposits in the liver and peritoneum should be rapidly investigated and a decision made on the possibility of its future removal. If the decision be in the affirmative the incision is closed and caecostomy performed as above; only in exceptional cases, where distension is comparatively slight and the general condition good, can an artificial anus be avoided by lateral anastomosis sufficiently far away to allow of a radical extirpation of the growth and its corresponding lymphatic area factor on such as ileo-sigmoidostomy for growths between the caecum and descending colon. If it be decided that the growth is inoperable, short-circuiting is preferable to an artificial anus whenever the bowel distal to the growth is readily accessible, but, as already explained, ileo-caecostomy (unless combined with appendicectomy or caecostomy) should never be employed as a permanent condition in malignant obstruction of the colon. Short-circuiting is frequently impracticable, in which event colostomy just above the growth is required, either in the sigmoid, transverse colon, or caecum according to the site of obstruction. For transverse colostomy the upper end of the original incision is utilized, but for either sigmoid colostomy or ileo-caecostomy a new incision is made in the abdominal wall, the growth is removed, and the operation is closed. If a definite decision as to the future operability of the growth cannot at once be made it should be regarded, for the time being, as operable, and the question finally determined at a subsequent exploration after the subsidence of all acute obstructive symptoms; then, if found inoperable, either a short-circuit or a permanent colostomy in some site less objectionable than the caecum may be practicable, the temporary caecostomy being allowed to close. It is agreeably surprising how frequently growths which at first appear to be too fixed for radical removal can with ready perseverance be ultimately mobilized and excised—indeed, local fixity is but rarely a contraindication to radical operation. Should the cause of the obstruction prove to be other than growth, various procedures may be requisite, such as division of constricting bands, the untwisting of a volvulus combined with its fixation by caecostomy or sigmoidostomy, according to whether the caecum or sigmoid is concerned, or, if the latter be already gangrenous, its immediate resection with drainage of both ends of the bowel by Paul's tubes.

In the most desperate cases of this group no attempt to find the obstruction should be made. Under local anaesthesia the caecum is exposed through a right "gridiron" incision, and, if found distended, is immediately opened ("blind" caecostomy); it collapsed, and distended coil of human that presents is opened and drained. In the latter event he deliberately takes the risk of leaving a strangulated nodule of bowel to later perforate and cause death from peritonitis, of opening the small intestine so high up that death from inanition is probable, or of overlooking some very easily removable cause of obstruction such as an impacted gall stone. Our justification is that occasionally a life is saved against which any further "interference" would have turned the scale, although such will almost certainly be required later, should the patient survive.

If the obstruction can be located to the colon but its actual site remains undetermined, then, provided external hernia and intussusception can be excluded, there is, as shown by the Manchester Royal Infirmary statistics, a 9 to 1 chance of the cause being a malignant growth, and a 6.5 to 1 chance of its being situated on the left side. In the very severe cases of this group I think it will be generally agreed that "blind" caecostomy under local anaesthesia is the proper procedure. On the other hand, in slight

indeed considered it desirable that the old terms "consumption" and "phthisis," which were removed from the official Nomenclature of Diseases (1918) in favour of "pulmonary tuberculosis," should be reinstated. The success of the Grancher method of protecting infants and young children from tuberculous parental infection was described by Dr. G. Brookes Dixon, who approves the use of tuberculin injection for infants thus exposed when separation was not allowed.

While the importance of early diagnosis and efficient treatment by rest at the outset, as described by Dr. Clive Riviere, must be universally accepted, it is also obvious that in the anxiety to secure this ideal there is the real danger of sweeping into the net people who are free from tuberculous infection. This risk of erroneous diagnosis has been estimated to be as high as 60 to 75 per cent. of the cases, and has recently been insisted on by Sir James Kingston Fowler, who has not concealed his critical attitude to modern conceptions of hilum tuberculosis. Dr. Riviere lays much stress on hilum infection, and, indeed, considers that in adult life pulmonary tuberculosis may be due to an extension of this infection from the glands at the root of the lungs, an opinion certainly difficult to establish against the alternative of later and independent infection by inhalation. As early diagnosis in cases in which the result of examination of the sputum is negative is uncertain, and radiograms are subject to fallacious interpretation, the help of the complement fixation test would be most welcome. From their critical survey, based on some 2,500 tests in pulmonary cases and controls and on a review of the literature, Drs. Punch and Gosse conclude that the variability of the results obtained can be partially explained by the different antigens employed. They reiterate their opinion, also entertained by Dr. Sellers, that a positive result indicates an active tuberculous lesion, and that with a few rare exceptions (2 to 3 per cent.) such as very acute, advanced, and moribund patients, a negative reaction is trustworthy evidence of the absence of such lesion. This is a much more assuring statement than that of Aronson and Lewis<sup>1</sup> that the application of the reaction in practice is limited by their observation that 10 per cent. of clinically normal persons give a positive action.

The methods of treatment considered are mainly those of comparatively recent date. In his exhaustive and interesting account of artificial light therapy Dr. Axel Reyn recalls Finsen's principle of the two distinct forms of this kind of treatment—the local concentrated action through lenses designed to destroy bacteria and produce inflammation, and the irradiation of the entire body or the light bath—to obtain the stimulating effect on the organism as in surgical tuberculosis; this last was started and early employed by Rollier, for Finsen's death occurred before he could finish his work on this subject. Dr. Axel Reyn does not accept Rollier's opinion that well marked erythema of the skin should be avoided; he believes that the best results are obtained from a light bath if pronounced erythema is produced in the earliest stages of the treatment. For lupus vulgaris the best treatment, as is shown by Dr. Sequeira, is a combination of the local and general light treatment—of concentrated actinic light to the lesions and the exposure of the nude body and limbs to the rays of a large arc lamp.

The discussion on the surgical treatment of pulmonary tuberculosis, introduced by Dr. Gravesen of the Vejleffjord Sanatorium, dealt with artificial pneumothorax and thoracoplasty. In the presence of pleuritic adhesions, which interfere with the efficacy of

an artificial pneumothorax, there is a choice between thoracoplasty and Jacobaeus's method of thoracoscopy with endopleural division of adhesions by the cautery. From considerable use and experience of Jacobaeus's procedure Dr. Gravesen sympathetically estimates its value, but concludes on the whole in favour of thoracoplasty for most cases with pleuritic adhesions; Dr. Burrell also agreed that very few cases were suitable for treatment on the lines practised by Jacobaeus. In the course of his opening paper Dr. Gravesen made an interesting digression to point out that, as the outcome of his experience with artificial pneumothorax, he had now adopted as part of the usual method of evacuating pleural effusions, both serous and purulent, the production of an artificial pneumothorax. Among other advantages this tends to prevent the formation of adhesions.

## OPERATIVE TREATMENT OF MITRAL STENOSIS.

THE ambitious efforts of surgery to remove conditions which physicians are unable to cure has been extraordinarily successful in the comparatively recent past, but hitherto valvular disease of the heart has remained outside the sphere of those who have been described as "physicians who can use their hands." More than twenty years ago the late Sir Lauder Brunton<sup>1</sup> published a "Preliminary note on the possibility of treating mitral stenosis by surgical methods," and, fortified with all the experience of thirty-five years of laboratory work, took out a vivisection certificate and licence to investigate this subject. This novel suggestion was, perhaps not unnaturally, regarded as a somewhat "heroic therapeutic measure," and raised a number of *a priori* objections; but it was not without some supporters. Sir Arbuthnot Lane<sup>2</sup> wrote that some years previously, having gone fully into the matter and concluded that the operation was feasible, he had mentioned it to his colleague Dr. Lauriston Shaw,<sup>3</sup> and had been prepared to act as soon as Dr. Shaw succeeded in finding a case likely to be thus benefited. Dr. Shaw confirmed this conference, which took place about 1890, but added that the *a priori* arguments against operation had appeared so convincing that he had abandoned the idea. At the same time Dr. D. W. Samways<sup>4</sup> pointed out that four years previously he had suggested notching of the stenosed mitral valve as a surgical method of treatment. Experimental surgery then became active in the production of valvular lesions in animals by cutting the aortic or mitral valve segments by a small knife introduced either into the aorta or into the left auricle (Tuffier, Carrel, Cushing, Allen and Graham). Sir Lauder Brunton's suggestion, however, appears to have inspired too much apprehension to be followed except by Doyen, whose patient did not survive the operation. In 1919 H. Vaquez<sup>5</sup> referred such a case to Tuffier, but no operation was carried out, and there have probably been many similar consultations.

A milestone has therefore been reached by the recent publication of a paper by Drs. E. C. Cutler and S. A. Levine<sup>6</sup> entitled "Cardiotomy and valvulotomy for mitral stenosis: experimental observations and clinical notes concerning an operated case with recovery." This

<sup>1</sup> Aronson, J. D., and Lewis: *Amer. Journ. Tuberc.*, 1923, vi, 1024.

In the most severe cases I perform a "grignon" sigmoidostomy, as the sole procedure, without any examination of the growth or liver from within. (b) and (c) Here the growth is too highly situated to be felt per rectum, so that we cannot, prior to its exposure by laparotomy, exclude the possibility, should it prove inoperable, of there being a sufficient and readily accessible length of bowel distal to it to permit of a short-circuit operation and thus avoid a permanent artificial anus. In these cases, therefore, I prefer caecostomy for the immediate relief of obstruction, so leaving the field clear for a later exploratory laparotomy (right or left paramedian according to the known situation of the growth), when either resection, short-circuit, exclusion, sigmoidostomy, or transverse colostomy may be feasible, in this order of preference; if none are practicable the incision is closed and the caecostomy left as the permanent condition, though for reasons already stated every effort should be made to avoid this.

Space does not permit me to consider technical details of the various operative measures alluded to, now for the most part standardized, nor to emphasize the extreme importance of the pre- and post-operative management of the case. Though I have laid stress upon what I believe to be the correct principles in the treatment of colonic obstruction once it has developed, yet it is to the earlier recognition of its most frequent cause—malignant growth—prior to the onset of this very serious complication, that our attention in the future should be increasingly attracted.

# DISCUSSION.

Mr. SEYMOUR BARTKOW (Birmingham) said that apart from such a special condition as volvulus, obstruction of the colon was rarely of that acute nature seen in the higher parts of the alimentary canal. It was true that occasionally a colon, that has been narrowed insidiously, became suddenly obstructed in its lumen, yet in the majority of cases the obstruction was subacute or chronic in its initial course. During the period of this partial obstruction such disturbances of function as pain, flatulence, and constipation might occur and be of assistance in arriving at a diagnosis. Frequently, however, no treatment was sought until vomiting and distension indicated the terminal stages of obstruction. Obstruction was much more common in the distal than in the proximal colon, for not only were growths and inflammations more common in that portion of the bowel, but the more solid nature of the bowel contents standing the hypertrophied and dilated colon proximal to the obstruction. In cases of obstruction of long standing the observation became filled with an insupportable mass of faeces, a condition most unfavourable to operative treatment. No one method of treatment was applicable to all the diverse conditions that might be met with in the group of cases which was being discussed. Consideration had to be paid to the site of the obstruction, to the condition of the patient, whether he was dying in the last stages of a chronic obstruction that had become acute, or whether the relief was partial and early, and, finally, whether the relief to be obtained was a permanent measure, or the first stage, preparatory to the removal of the affected segment of bowel. Caecostomy was undoubtedly the method of choice in patients who were the worst operative risks of all, the distended patient who had been vomiting for some days. In such cases, when diagnosis was certain, the caecum could be opened under local anaesthetic with the minimum of risk, and such operation was sufficient to tide the patient over the condition of toxæmia which constituted his greatest danger. Moreover, it relieved obstruction in whatever part of the colon it was arising, with the exception of the occasional growth at the ileo-cæcal valve. This operation was a lifesaving measure, for if these patients were submitted to a laparotomy, partly exploratory and partly for performing a colostomy, a very large percentage died. If by means of a

May 24th, 1932.  
An excellent paper by E. R. Flint, *Barnes Medical Journal*.

Mr. A. B. MITCHELL (Belfast) said that the cases of colonic obstruction were among the most difficult of all surgical problems. The greater their experience the more conservative surgeons became. The enthusiasm and desire for a complete operation, so characteristic of their earlier surgical work, was highly dangerous. It was their misfortune if their first operation of this kind was a success, as it was certain to lead to future fatalities. The mere opening of these cases of acute obstruction, with the necessary handling and control of the intestine, was a dangerous operation, likely to result in a rapid increase of the toxæmia. In the acute case the less the surgeon did the better; Mr. Mitchell was all in favour of a rapid caecostomy under local anaesthetic. In milder degrees of obstruction, if the conclusion had been reached that future excision was impracticable, then a lateral anastomosis was the best procedure. If a permanent colostomy had to be performed, it was imperative that the incision be made in a site where the growth was not likely to recur. In the acute case the less the surgeon did the better; Mr. Mitchell was all in favour of a rapid caecostomy under local anaesthetic. In milder degrees of obstruction, if the conclusion had been reached that future excision was impracticable, then a lateral anastomosis was the best procedure. ## THE UNIVERSITY OF TOKYO.

THE recently published transactions of the Medical Faculty of the University of Tokyo<sup>1</sup> afford good evidence of the activity of that university in the matter of scientific research. They contain more than 600 pages, and the sixteen papers are all of value and some of more than ordinary interest. Omori discusses the question of cardiac inhibition as exhibited in the contractions of the sinus venosus, a part of the heart hitherto very little studied in this connexion. The experiments were made on the heart of the toad, the preparation consisting of a strip of the isolated sinus. He employed both intra- and extra-cardiac stimulation of the vagus, the former by means of muscarin, the latter by electrical stimulation of the nerve trunk, and the contractions were studied under varying degrees of stimulation and in varying metabolic conditions, induced by alteration of the temperature and the tension of the muscle. Among the results observed were the following: (1) The energy and metabolism of contraction are a function of the tissue tension, as in other parts of the heart; (2) the action of the vagus is a function of the tissue tension, and the increase and decrease of the inhibitory action are inversely proportional to the degree of tension, and consequently to the metabolic activity; (3) in favourable metabolic conditions the inhibitory action disappears and acceleration occurs, the evidence pointing to its being due to vagus stimulation; (4) the contractions of the sinus are regular at temperatures between 1° and 35° C., but show a gradual increase between 5° and 30° C., represented on the myogram by a straight line and indicating a metabolic activity increasing with the temperature; (5) the action of the vagus is a function of the sinus temperature; increase and decrease of inhibition stand in inverse relation to rise of temperature—that is, to the metabolic activity; (6) in favourable metabolic conditions inhibition disappears and is replaced by acceleration. Omori inclines towards Verworn's theory of dissimilation; he imagines an automatic centre outside the contractile substance, the rhythmical activity of which may be affected by vagus stimulation interrupting the rhythmical stimuli (stillstand), slowing the rhythm (chronotropism), or by acceleration, the diminution in contractile power then observed (inotropism) being associated with a partial dissimilation palsy of the muscle, leading to smaller and shorter contractions. Gytoku and Momose have a paper on the metabolism of four cases of Addison's disease. Their general conclusions are: (1) that there is never any marked hypoglycaemia; in one severe and fatal case there was a slight decrease in the blood sugar as the general condition deteriorated; (2) that the action of adrenaline as regards pulse and blood pressure is similar to that in the healthy subject; (3) that the alimentary glycaemia occurring in Addison's disease is the same as in the healthy subject; (4) that with regard to protein metabolism, the nitrogen balance was negative in the two severer cases, and positive in the two slight cases; no definite conclusion could be reached as to whether an increase or decrease was the rule; (5) in all cases there was a marked negative balance for calcium and a positive balance for phosphorus. Kira contributes a paper on the rapidity of *post-mortem* autolysis of glycogen in the liver. He used the toad and the rat as examples of cold-blooded and warm-blooded animals respectively. In the former glycogen disappeared very slowly, and no marked difference was observed as between the hibernating and the waking conditions. In the rat the rate of disappearance was greater but not markedly so, and the author's experiments seemed to show that the difference was due, not to any difference in the amount of diastase present, but to a greater stability of the

glycogen in the toad. Other papers deal with the healing-in of foreign bodies in the lung, and the epithelial hyperplasia associated with it; calcium and magnesium metabolism, more especially in relation to the percentage of these compounds in the blood; the influence of the thymus on the growth of bone; the virus of rabies; diabetes and the haemolytic action of glucose; gastric secretion and hyperacidity; the cerebro-spinal fluid; primary diseases of the lymphatic system; Schede's operation for empyema; and the pathogenesis of circulatory failure in pneumococcal pneumonia. No man of science in this country or indeed in the whole world can turn over the pages of this volume without a feeling of intense sympathy with these fellow workers in the cause of humanity in the tragedy that has overwhelmed their city. The Japanese have always been regarded by us Westerners as born masters in the fine arts, and foremost in the genuine love of Nature; and the manner in which they have, in recent times, stepped forward into the line of modern scientific progress is one of the wonders of the age. The calamity that has befallen them will be felt as a calamity to the whole world.

## A HOSPITAL HEALTH CENTRE IN WALES.

CARDIGAN has set an example which may well be imitated by other towns not only in Wales but in England; it has established what practically amounts to a health centre such as was conceived in the report of the Consultative Council of Medical and Allied Services, presided over by Lord Dawson of Penn. It may be described, perhaps, as a cross between a primary and a secondary health centre as outlined in that report. It has the cordial support of the medical profession in the district and the great advantage of the services of Sir John Lynn-Thomas, who resides in the neighbourhood and acts as a consulting and operating surgeon; it can also command the assistance of Mr. Wade of the Cardiff Royal Infirmary. The Cardigan and District War Memorial Hospital, founded less than two years ago, has been for the present completed by the establishment of an out-patient department and clinics. The clinics will include child and maternity welfare, and tuberculosis. The new buildings were opened last week by Mrs. Lloyd George, when a public meeting was held under the presidency of Mr. John Evans, chairman of the Hospital Executive Committee, who referred to the gift of x-ray apparatus made by the ex-service men of the district. He also mentioned that a motor ambulance station had been established in the yard of the hospital through the gift of an ambulance by the Joint Ambulance Committee of the British Red Cross and the Order of St. John. A short address on the maternity and child welfare scheme was given by Dr. Meredith Davies, M.O.H. for Cardiganshire, who said that the infant mortality for the county had declined from 130 in 1911 to 60 in 1920; this he attributed to the operations of the child welfare scheme. He also spoke of the importance of the maternity work for the expectant mother, and prophesied that in a short period all confinements would take place in hospitals. After a short speech from Mr. Ernest Watkins, secretary to the Welsh Department of the Ministry of Health, Dr. Lloyd, county tuberculosis officer, congratulated the Committee and the people of the district on behalf of the Welsh National Memorial Association. The hospital and the clinics formed a fitting memorial for the glorious dead, and would be a lasting memorial also to Sir John Lynn-Thomas, who had not only taken a large share in the foundation and organization of the hospital, but had placed his skill as an operator at its disposal. Dr. Lloyd went on to say that the mortality from tuberculosis was steadily declining in the county; in the period 1875 to 1914 the average was 2.8 per 1,000; last year it was 1.63. Dame Margaret Lloyd George, who was very cordially received, said that she first visited the hospital some fourteen months

<sup>1</sup> *Mitteilungen aus der Medizinischen Fakultät der Kaiserlichen Universität zu Tokyo*. Tokyo: Kaiserlichen Universität. Band XXIX, Heft 2 (Imp. 8vo, pp. 420). Band XXIX, Heft 3 (Imp. 8vo, pp. 422-624; illustrated). Band XXX, Heft 1 (Imp. 8vo, pp. 205; illustrated).

departments and small special hospitals poorly equipped and with few facilities for scientific work. He was impressed by the system of clinical records, with its stenographers, clerks, and filing arrangements. Many American surgeons, like Dr. Crile, combine a large amount of research work with their operative practice, and for this purpose they find the clinic system very valuable. At Chicago the College of Surgeons publishes a clinical bulletin daily, showing all the operative work going on in the city. The college also has a department of literary research, which for a small fee will supply a complete bibliography with abstracts of any subject in medicine or surgery. Everywhere, both in the United States and in Canada, Mr. Webb-Johnson saw the utmost keenness and thoroughness coupled with perfect equipment and organization. But he did not observe the same relationship between the student and the patient as there is between the clerk or dresser and the patient in British hospitals. The schools excel in the spirit of research, and the hospitals are far ahead of ours in the care they give to their records.

#### SOME POINTS OF VIEW ABOUT VACCINATION.

EVERY week brings us a batch of newspaper cuttings about vaccination, and the recent circular issued by the Ministry of Health has not diminished their number. A short time ago (July 14th, p. 72) we discussed the duty of the medical profession in respect of vaccination propaganda in connexion with the appeal then recently made by the Bishop of Gloucester, and pointed out that the British Medical Association has constantly advocated a sound vaccination policy, has made representations on the necessity for more thorough vaccination of the community, has lent its support to suitable propaganda, and has supplied information to inquirers. Meanwhile, as we have frequently observed, small-pox is itself the best teacher. One of the reports before us is to the effect that the chairman of a board of guardians in Essex recently remarked at a meeting that "many people take exemption papers, and don't understand it," in which view he had the frank support of an opposing member, who said, "I did, but I don't quite know why." On the question of the need for revaccination, another guardian used the apt illustration, "though a house has once been repaired it has to be continually kept in order, so there must be revaccination." Ultimately it was resolved without a dissenting voice "that the attention of the doctors be called to the importance of vaccination, and that they should encourage parents and patients to be vaccinated." Thus are the clergy and the laity appealing to the medical profession to support vaccination. In the House of Commons a short time ago, as reported in our Parliamentary Notes at the time, a Labour member protested against the efforts of employers in Gloucester to get their employees vaccinated, and rhetorically asserted "that he declined to allow an employer of labour, simply because he employed an individual, to utilize powers that were never given to him to compel his employees to be vaccinated," and he "appealed to the Minister to come to the rescue of these people." Lord Eustace Percy, replying for the Minister of Health, said that were he in Gloucester he would claim the right to protect his household from what he would consider a risk, by refusing to take into his employment anyone who was not vaccinated. It would be a rather gross form of tyranny, he continued, were the State to tell him that he was not at liberty to do so. This rejoinder reminds us of a piece of evidence given by an American witness before the Royal Commission on Vaccination. He told how when small-pox was feared the officials of a certain State would board an immigrant train before it reached that State and proceed to vaccinate the travellers. When, as occasionally happened, an English immigrant objected, a conversation

somewhat to the following effect would ensue: "I understand that vaccination is voluntary in this country." "Yes, certainly, this is a free country, stranger, you can be vaccinated or not as you please." This elicited the reply, "Well, I object to vaccination and I won't be done," to which the answer, "That's all right, we'll stop the train and let you off at the boundary of our State"; but, says the immigrant, "I don't want to be put off—I'm going into your State." "No, you're not, sir; you are a free man and refuse vaccination; we are a free State and refuse to admit the unvaccinated." "Well, what town do you let me off at?" "No town at all—there's none near the border. Oh! you do want to get vaccinated?—surely—which arm? Thank you—next please." That is not exactly the story, but only the gist of it, and similarly the Ministry of Health holds that the employer, as well as the employee, is a free man. Thus the great Republic of America and the conservative Government of Britain seem to hold identical views; whilst the American Eagle, the bird of freedom, winks to the British Lion, as they jointly witness this display of international agreement.

#### THE WORK OF A MATERNITY DEPARTMENT.

A CLINICAL report for 1922 of the maternity department of the Jessop Hospital for Women, Sheffield, has been prepared by Dr. J. Eric Stacey, the registrar. The total number of cases treated by the hospital during the year was 887; of these, 700 were treated in the wards; of the 618 delivered in the wards 203 were primiparae and 415 multiparae; primiparae are not attended in the "district." The maternal mortality was 14 (2 per cent.); 67 patients were discharged undelivered. The number treated in their own homes was 187. The hospital admits cases from the outlying districts, and no case has been refused during the year where application has been made by a medical practitioner. Many of such cases have been sent in after attempts at delivery in their own homes have been unsuccessful. The maternal morbidity (including the 14 deaths), calculated on the basis of deliveries (618) and not on the admissions, was 7.9 per cent. British Medical Association standard and 16.6 per cent. Queen Charlotte's Hospital standard. Among the 618 deliveries there were 11 cases of twins, 33 breech presentations, 10 transverse lies, 14 prolapse of funis, and 10 face and brow. There were 25 cases of placenta praevia, with no maternal death; 10 of the children were stillborn; there were 16 cases of accidental haemorrhage, including 4 of the concealed type, in one of which latter, where delivery was effected by Caesarean section, the mother succumbed; 9 of the children were stillborn. Out of the 147 cases of contracted pelvis treated in the hospital, 27 were delivered by forceps, 22 by Caesarean section, 7 by craniotomy, 2 by decapitation, 4 by version, and in 2 cases labour was induced; 21 children were stillborn. Caesarean section was performed on 33 occasions with 2 maternal deaths (the case of concealed accidental haemorrhage noted above and a face presentation who later died of sepsis). In 2 cases of concealed accidental haemorrhage delivered by this method the child was stillborn; 15 cases of eclampsia were admitted, and 4 of the mothers died. The deaths among the 629 children (including premature infants) born in the hospital numbered 95; of these 46 full-term children and 24 premature infants were born dead, the remaining 5 died after birth. No account is taken in the report of those cases of ectopic gestation, abortion, hydatid mole, hyperemesis gravidarum, and other complications of pregnancy in which the gestation period was less than seven months, as cases in this category are treated in the gynaecological wards of the hospital. A short summary is, however, given of the operations performed in the gynaecological department.

completely diverted the faeces, thus freeing the bowel at the future site of resection and anastomosis from gross contamination, which he maintained could not be done by caecostomy. A fortnight later he carried out the excision, and several weeks later closed the colostomy by the intraperitoneal method. In a growth proximal to the splenic flexure a caecostomy had to be performed.

Mr. C. P. CHAPPEL (Forsmouth) remarked that there was a difference of opinion as to the proper course to pursue in any given case of acute obstruction due to colonic disease. It was of great advantage to get rid of the obstruction. Opening the bowel above the obstruction—that was to say, the last being to close the temporary opening. He would care to perform blind caecostomy only if the patient were exceedingly ill and unable to bear anything but the slightest operative interference. If the patient were ill to a less degree he would endeavour to locate the obstruction, as by means his after-treatment would be on safer ground, and he would then know what kind of growth he was dealing with and where the growth was situated.

Mr. R. D. MORTIMER-SOLE (Bolton) was of opinion that there would be general agreement as to the advisability of doing the least serious operation, probably caecostomy, in the worst cases of acute obstruction. But the position of the caecostomy was more doubtful. In his own practice he had been better satisfied with those cases in which he had done a preliminary colostomy than in those in which he had done a caecostomy. Most surgeons would agree that the mortality of operations for cancer of the rectum was much lessened by putting the diseased bowel out of action by a preliminary colostomy. The same should hold good with regard to other portions of the bowel, and he suggested that the mortality of the operation would be lessened by doing a caecostomy for relief of obstruction and the excision of the malignant disease.

Mr. M. MAMOURIAN (Ashton-under-Lyne) said that Mr. Burgess emphasized rightly the value of "blind" caecostomy as a valuable life-saving device. The decision as to whether a patient should be submitted to blind caecostomy or to a preliminary exploratory laparotomy would depend upon the condition of the patient. Where the patient's condition warranted it, exploration of the abdomen, which was the procedure indicated. Mr. Mitchell referred to the inability one to localize and diagnose the obstructing lesion, bringing the junction of the proximal loop to the iliac wound, method of colostomy by closing the distal segment and leaving the loop out so as to get an opening big enough to admit two fingers. The fixation of the loop or tube was rendered easy with one hand in the abdomen and the guidance of the eye. By this technique the calliblower-like provision was avoided, and the opening was certainly more satisfactory than the one made on muscle-splitting lines. Mr. Lockhart-Mummery had referred to his method of caecostomy by the use of a rubber tube. Mr. Mammourian wished to draw attention to another extremely easy method of performing caecostomy or colostomy, by the use of the Murphy button, which he had published about ten years previously. The piece of half of the button was inserted at the end of a long piece of soft colostomy tubing, and the collar and the collar of the button just as if it were a piece of bowel. A linear purse-string suture was put in the bowel, the incision made, and the other half of the button placed in position. The two halves were pressed together, and thus an hermetically sealed joint was established between bowel wall and tubing. The button took four or five days to separate. It was a quicker, safer, and neater device than the Paul's tube. Mr. Burgess, in reply, considered that there had been shown in the discussion a fairly general agreement upon most of the points he had raised, the most debatable

other cases of carcinoma of the colon. A patient with chronic obstruction was given an opaque enema. The radiographic picture was given an opaque enema. The radiographic picture was shown in Figure 3. It was reported to give no evidence of stricture of the colon. Four days later he got acutely obstructed and, when opened, there was found a narrow annular growth of the sigmoid. Obviously there the last being to close the temporary opening. He would care to perform blind caecostomy only if the patient were exceedingly ill and unable to bear anything but the slightest operative interference. If the patient were ill to a less degree he would endeavour to locate the obstruction, as by means his after-treatment would be on safer ground, and he would then know what kind of growth he was dealing with and where the growth was situated.

Mr. J. W. GEARY GRAY (Cardiff) said he had been greatly interested in Mr. Burgess's paper. Every surgeon, of course, agreed that a primary resection with end-to-end union was a totally unjustifiable procedure. The Mikkelsen operation had more to be said in its favour, but the chief objection was that it did not permit of an extensive removal of the lymphatic area. He was interested to hear Mr. Lockhart-Mummery's description of his method of caecostomy, which he would certainly try in the next suitable case, for he was bound to say that his own experience of caecostomy had been most unsatisfactory. In two cases where he tied in a small Paul's tube leakage took place, with excessive suppuration and sloughing of the abdominal wall. Caecostomy did not appear to him such a simple procedure as it had been represented to be, and he gathered that Mr. Pannett was somewhat of the same opinion. The whole point was that while a Mikkelsen operation, which seemed to be the principle of Mr. Mummery's factor in these cases. He had not seen an exploratory laparotomy, if carefully carried out—of course not letting any marked increase of shock, which was due to stretching of the gut and absorption of toxins. What he had been struck with was the great amelioration of symptoms a few hours after. In obstruction from the splenic flexure to the recto-sigmoid junction, he made a transverse colostomy and

## Obituary.

DR. ERNEST MORLEY ROOKE died at Brighton after an operation on September 10th, aged 57. He was the second son of the late Dr. T. M. Rooke of Cheltenham, and was educated at Guy's Hospital Medical School, and took the diplomas of L.S.A. in 1891 and M.R.C.S. and L.R.C.P. Lond. in 1892. He served as a civil surgeon in South Africa in 1899-1900, receiving the Queen's medal with two clasps; was for several years chief medical officer of the Bengal-Nagpur State Railway in India; and held a temporary commission in the R.A.M.C. in 1915-16. He was vice-chairman of the National Service Medical Board for Sussex.

DR. ALFRED GEORGE WILKINSON, a veteran practitioner, of Northampton, died on September 15th, aged 88. He took the diplomas of M.R.C.S. Eng. in 1857 and of L.S.A. in 1866. While still a student he went to the Crimea as a dresser, and worked with Florence Nightingale; he assisted in attending the wounded after the charge of the Light Brigade. Dr. Wilkinson settled in practice in Northampton in 1870, and he continued at work until a few days before his death.

DR. WILLIAM FLETCHER GIBB of Paisley died on September 11th, aged 67 years. He was the son of the late Mr. Andrew Dewar Gibb. From Paisley Grammar School he went to the University of Glasgow, where he graduated M.B., C.M. with commendation in 1883, and M.D. in 1885. He also studied in Vienna. He served as house-surgeon to the Western Infirmary, Glasgow, and assistant physician to the Glamorganshire County Asylum before commencing practice in Paisley. He had held the appointments of medical officer to the West Kilbride Convalescent Home, consulting surgeon to the Royal Alexandra Infirmary, Paisley, and certifying factory surgeon. When the war broke out Dr. Gibb deputized for other local medical practitioners who were called up for military duties, and he also gave daily service at the Bellahouston Hospital. His kindly manner inspired great confidence in his patients.

DR. JOHN McMURRAY died at his residence in Bootle on September 12th, in his 66th year. He graduated M.D., R.U.I., M.Ch., and L.M. in 1882, and three years later took the degree of M.A.O. He was senior scholar in therapeutics and pathology at Queen's College, Belfast, in 1881-2, and obtained honours in his university examination. He was a justice of the peace for the borough of Bootle, and mayor of the borough in 1897-98. Dr. McMurray was visiting medical officer to the Liverpool Industrial Schools and the Liverpool branch workhouse, and had served as honorary surgeon to the Bootle Borough Hospital, senior resident medical officer to the Liverpool Parish Infirmary, and house-surgeon to the Northern Dispensary, Liverpool.

We regret to announce the death on September 17th of DR. MARGARET L. A. BOILEAU, aged 56. She was the only daughter of the late Sir Francis Boileau, received her medical education at the London School of Medicine for Women, and graduated M.B., B.S. Lond. in 1906. She afterwards served as clinical assistant in the out-patient department of the Elizabeth Garrett Anderson Hospital for Women and for some time was in practice at Ravenscourt Park. During the war she acted for a short time as house-surgeon at the Jenny Lind Hospital for Children. She was commandant of the V.A.D. Hospital at Swainsthorpe, and for several years during the war and subsequently she gave gratuitous assistance to the infant welfare clinics of the Norwich Corporation. She was a member of the East Norfolk Division of the British Medical Association. She took great interest in the Girl Guide movement, the work of the Church Missionary Society, and the Young Women's Christian Association.

with ether but none of them have abdominal or other operations likely to interfere with efficient respiration.

Mr. Colt's suggestion of a tonometer to measure muscular relaxation would, I fear, prove impracticable. I know few surgeons who would willingly attach one to their retractor and, of course, with good ether relaxation such an instrument may be unnecessary. If attached to a group of muscles at a distance the information would be of slight value, as if Mr. Colt will carry back his thoughts to those far-off anaesthetic days he will remember that relaxation in one set of muscles does not necessarily imply it in another. Many surgeons are themselves tonometers of excessive delicacy.—I am, etc.,  
London, W., Sept. 11th.

CHARLES F. HADFIELD.

## PAY OF THE R.A.M.C.

SIR,—In the recent Educational Number of the BRITISH MEDICAL JOURNAL there appears, under the heading of Public Services, a lengthy notice concerning the pay for the Army Medical Services. This has doubtless been perused by many officers of the corps with astonishment, and probably also by would-be applicants with high hopes.

My reason for writing is to ask from what source these figures came, as they will be disputed by those officers already serving in the corps if they take the trouble to work out their incomes. Again, they can be disputed by the Army Estimates for the year 1923-24 printed on March 5th, 1923, which gives the total maximum for lieutenants up to major-generals. It will be seen at once that those given in the article in question do not in any case agree with those in the Army Estimates, which include all pay except specialist and extra duty pay.

I give the 1923-24 estimate:

|                               | Married. | Unmarried. |
|-------------------------------|----------|------------|
| Lieutenant                    | £ 598    | £ 532      |
| Captain                       | 738      | 646        |
| Captain after 6 years         | 756      | 665        |
| Captain after 10 years        | 811      | 719        |
| Major                         | 884      | 824        |
| Major after 15 years          | 975      | 916        |
| Lieut.-Colonel                | 1,157    | 1,107      |
| Lieut.-Colonel after 20 years | 1,203    | 1,153      |
| Lieut.-Colonel after 25 years | 1,249    | 1,198      |
| Colonel                       | 1,471    | 1,407      |
| Major-General                 | 2,140    | 2,074      |

I consider the article most misleading, especially as allowances have been lumped together with pay; this is contrary to the meaning of paragraph 272—Allowance Regulations, which states: "Lodging money is not a personal emolument"; if it is not personal, it cannot be regarded as income.

Again, all allowances of those drawing specialist pay are taxable where the specialist holds a fixed appointment, and as most specialists' appointments are now fixed he who should get 5s. a day only gets 2s. 1d. a day, and he who should get 2s. 6d. extra gets 5d. This also holds good for allowances in other cases where the appointment is considered by War Office to be of a fixed nature.

I enclose my card, but not for publication for obvious reasons.—I am, etc.,

September 8th.

AN ARMY DOCTOR.

\*\* The information published was supplied to us by the War Office.

DR. V. NOQUET of Lille, one of the pioneers of laryngology, and President of the French Society of Oto-rhino-laryngology in 1901, has recently died at the age of 76.

With the proceeds of the "Golden Casket" lottery, which amount to some £200,000 per annum, maternity hospitals and ante-natal and child welfare clinics are to be established throughout Queensland, under the provisions of a new Maternity Act passed at the last session of the Queensland Parliament. Maternity hospitals will be established in isolated places, and sums varying from £2,500 to £10,000 will be used for the provision of adequate institutional accommodation in the ten largest towns of Queensland.

557 THE BATTLE MEDICAL JOURNAL

[illegible]

## Letters, Notes, and Answers.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

As, owing to printing difficulties, the JOURNAL must be sent to press earlier than hitherto, it is essential that communications intended for the current issue should be received by the first post on Tuesday, and lengthy documents on Monday.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

In order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL.

The postal address of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is 429, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Aitology Westrand, London*; telephone, 2630, Gerrard.
2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westrand, London*; telephone, 2630, Gerrard.
3. MEDICAL SECRETARY, *Medisecra Westrand, London*; telephone, 2630, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone, 4737, Dublin), and of the Scottish Office, 6, Rutland Square, Edinburgh (telegrams: *Associate, Edinburgh*; telephone, 4361, Central).

### QUERIES AND ANSWERS.

"MEDICUS" asks for references to the treatment of periodic dipsomania and alcoholism by psychotherapy.

#### CLEARING THE THROAT.

"L." asks for suggestions in the treatment of a medical man, aged about 45, who suffers from continual attempts at "clearing of the throat" owing to undue secretion of mucus in the larynx. It is increased in cold damp weather and on dusty roads, lessened (or entirely absent) when lying down in bed. The condition makes talking a trouble and an exertion, and it much interferes with the strength and tone of the voice. During an actual attack of acute laryngitis there is no desire to "clear the throat"; only when the acute stage has passed off does it recur.

#### SYMPATHETIC MAGIC?

WITH reference to the note under this heading (September 15th, p. 490), in which a correspondent stated that he had been asked whether stuffing a pad of cotton-wool into the mother's umbilicus would kill the child by suffocation, Dr. M. Cursham Corner (Mile End Road, London, E.) writes: I think the condition or sentiment arises from the common idea in this neighbourhood of wearing a pad of sheep's wool tied in a bandage so as to fit over the umbilicus; the reason given to me by the mothers is to keep the infant warm.

#### TYPHUS AND TRENCH FEVERS AND THE LOUSE.

PASCAL.—The wording of our correspondent's inquiry as to the method of transmission of typhus fever and trench fever by lice is not quite clear. If it refers to the life-history of the parasite in the louse, there is no evidence at present to show the nature of any micro-organism that is the cause of trench fever; and doubt is being thrown on the theory that the so-called Rickettsia bodies found in typhus fever, and regarded as protozoal in character, are actually living organisms or a causative factor in that disease. If the inquiry refers to the mode of transmission from lice to man, this is the same for both diseases—namely, by the excreta of infested lice being rubbed into excoriations of the skin which are caused by scratching. It is only the body louse (*Pediculus vestimentorum*), and not the *Pediculus capitis* or *Pediculus pubis*, that is implicated. Infestation by the body louse occurs mainly through close association with verminous persons, especially when men sleep close together, but it may occur indirectly through clothes, bedding, combs, brushes, and other effects used by lousy individuals. Full information on the subject will be found in vol. ii, *Hygiene of the War*, chapter XII, of the series of volumes on the Medical History of the War, and also in chapters V and XVI of vol. i, *Diseases of the War*, of the same series. No fresh light has been thrown on the facts recorded in these volumes.

### LETTERS, NOTES, ETC.

A COUNTRY practitioner sends us the following couplet, headed Metabolism, Past and Present:

"Banting took our flesh away;  
Banting brings it back to-day."

#### HERPES AND VARICELLA.

DR. M. T. D. McMURRICH (Johnstone Bridge, Lockerbie) writes: In view of the supposed relationship between herpes and varicella the following case may be of interest. On August 22nd a man, aged 71, had an attack of herpes affecting the posterior surface of the pinna of the right ear and the angle of the jaw (the area corresponding to the distribution of the nervus auricularis magnus). On August 28th he developed chicken-pox, which ran a normal course. On September 11th his niece, aged 9 years, who lives with him, also developed chicken-pox. The fact that chicken-pox developed in a man over 70 years of age who was already suffering from herpes, seems to give support to the view that herpes and varicella are due to a common causal factor.

#### CONGENITAL DEFORMITY.

DR. JOHN WALKER (Paisley) writes to inform us of an exceptional case of birth that came under his notice. On September 4th, 1923, a woman was delivered of a female child having little or no vestiges of arms or legs. Of the right arm there was only a small portion of the humerus, and of the left arm even less. The right leg was completely absent, revealing only a slight projecting rotundity; but the left leg, in a similar shrunken state, took the form of a foot with but two toes appearing, the great toe and the next adjoining—and having no sign of thigh or leg. The head, neck, and trunk were perfectly normal and the child cried, sucked, passed meconium and urine, and has already lived eleven days, showing signs of natural development. The labour was a breech case; in birth the cord was cut before delivery of head, and no artificial respiration applied, yet the child survived. Dr. Walker adds: "The birth has been followed with keen interest, both by myself and assistant doctors and professors in the West of Scotland. It seems to me an extraordinary case, both in regard to the infant's early and vigorous vitality, as also to the supreme extent of deformity. I would be glad to get details regarding any similar cases, as also data of their later development."

#### A DISCLAIMER.

DR. E. ROWLAND FOTHERGILL (Hove) writes: My attention has been drawn to certain advertisements appearing in the JOURNAL for September 15th. This advertisement includes the phrase "Put your faith in a Fothergill," and I am asked "Are you breaking out in a new place?" Apart from the fact that any direct descendant of the Fothergills from Ravenstonedale, Westmorland, is bound to break out sooner or later somewhere—it being heredity—I would be glad of the opportunity to say I know nothing whatever about the advertisement nor the firm advertising. In support of this contention I would draw your attention to the word "a" in the quoted paragraph; an introduction into an otherwise complete sentence which I am sure you will agree those who know me would consider unnecessary, not to say disparaging, in its possible interpretation.

#### VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 33, 36, and 37 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 34 and 35. A short summary of vacant posts notified in the advertisement columns appears in the Supplement at page 110.

### SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

|                                             | £   | s.  | d.     |
|---------------------------------------------|-----|-----|--------|
| Six lines and under                         | ... | ... | 0 9 0  |
| Each additional line                        | ... | ... | 0 1 6  |
| Whole single column (three columns to page) | ... | ... | 7 10 0 |
| Half single column                          | ... | ... | 3 15 0 |
| Half page                                   | ... | ... | 10 0 0 |
| Whole page                                  | ... | ... | 20 0 0 |

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded. Advertisements should be delivered, addressed to the Manager, 429, Strand, London, W.C.2, not later than the first post on Tuesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *posté restante* letters addressed either in initials or numbers.

Dr. HENRY PETERSON, in reply, agreed with Mr. Childs that statistics might be very misleading, but in this instance statistics supported his own experience that the remote results of operation for carcinoma-to-day did not seem better than was the case twenty-five years ago. Sir St Clair Thomson was to be congratulated on the excellence of his results in laryngeal cancer. Mr. Peterson thought his statistics were of great value in showing what could be effected by early operation, and they were of special interest from the fact that in none of his cases were the lymphatic glands removed. It was significant that in only two instances were the glands subsequently the seat of new growth.

Dr. Bruce (Toronto), in speaking of propaganda, mentioned that in Canada, where methods of educating the people had been in vogue for some years, the effect was noticeable in so far as the people did go to the doctors with "specifics" much earlier than they formerly did. He advocated strongly the campaign for propaganda purposes, so as to educate the public in the early symptoms and signs of cancer, no matter where situated. The results of surgery had advanced enormously in Canada. Dr. Bruce cited a case in which excision of the tongue had been performed by the late Sir Henry Bustin, and years later.

STANDARDIZATION OF COMMERCIAL PREPARATIONS OF THE PARATHYROID GLANDS.

H. W. C. VINES, M.D.,  
 PATHOLOGICAL RESEARCH STUDENT,  
 (From the Pathological Laboratory, Cambridge.)

Such a state of affairs constitutes a very real drawback to the use of these extracts.

[illegible]

The commonest method of determining the concentration of commercial parathyroid preparations is given as briefly as possible, with the omission of details having a purely scientific bearing. It is hoped that a more detailed account of the reactions involved may be published later, but since it is impossible to standardize these preparations, at least to some extent, it is desirable that the method should be thoroughly tested and utilized while the preparations are in demand. It is generally held that the parathyroid glands have two functions; they regulate calcium metabolism and they are in some way able to prevent intoxication by guanidine and its derivatives. On this second property the standardization method is based. The principle is as follows; with a known amount of guanidine in solution, at the end of the incubation period is found to be less than at the beginning of the test. Only one function of the glands is therefore tested, but there is reason to believe that if the preparation is deficient in this function it will also be deficient in the other.

рочен

The following solutions are required:

3. An aqueous saturated solution of picric acid.

For the standardization of commercial preparations, the amount of weight for the test has been taken as 0.655 gram, or one grain of the desiccated powder. Where a tablet preparation has been tested, a sufficient number of the tablets has been used, according to the strength indicated on the bottle, to make up the unit weight of dried gland.

These figures show that there is a small error in the method of gauging estimation, but it is not sufficient to interfere when active parathyroid preparations are tested. The following figures indicate the necessity for adequate aeration of the test fluid; the same parathyroid preparation was used in each case under the standard test condition described above.

|                           |           |              |
|---------------------------|-----------|--------------|
| Substance.                | Recoverd. | Known Picate |
| Horse serum               | 210       | 220 mg.      |
| Leghmin                   | 216       | .....        |
| Acetone soluble fats from | 214       | .....        |
| parathyroid               | 126       | .....        |
| Iodized lecithin          | 263       | .....        |
| Unknown tissue            | 245       | 260 mg.      |

1. Control test.—Recovery of guanidine picrate from test solution where inactive substances other than parathyroid have been used.

[illegible]

The formula for the test solution is as follows:

## 211. Saline Injections in Gastro-enteritis.

M. HARPER (*Med. Journ. Australia*, June 23rd, 1923, p. 693) advocates the intraperitoneal method for saline injections in gastro-enteritis in infants as being free from the disadvantages frequently accompanying other methods of administration. It is easy to perform and causes very slight disturbance, amounts varying from six to eight ounces two or three times in twenty-four hours being rapidly absorbed, even in moribund infants, with resulting rapid and striking improvement. The usual signs of dehydration and collapse—for example, sunken eyes, depressed fontanelle, and loss of skin elasticity—are indications for its use, a distended abdomen being apparently the only contraindication, because of the danger of puncturing the bowel and the lessened readiness of absorption in such a condition. After ascertaining that the bladder is empty a somewhat blunt, short-bowelled needle is inserted in the middle line just below the umbilicus, and from 6 to 8 oz. of normal saline solution, with or without 5 per cent. glucose, are allowed to flow slowly, under gravity, for about fifteen to twenty minutes. Antidysenteric serum can be similarly administered as a true transfusion; and also freshly citrated blood, as a useful treatment in gastro-enteritis, may be so given when other routes are unavailable.

## Surgery.

## 212. The Diagnosis of Stone in the Kidney.

H. HOHLWEG (*Klinische Wochenschrift*, July 30th, 1923, p. 1447) points out that, until x-ray examination was employed, the diagnosis of renal calculus was based chiefly on colic and haematuria. Both may be absent, and both may occur in other diseases. Haematuria and pain after physical exertion are in favour of stone and against renal tumour. The diagnosis may be aided in hydronephrosis and pyonephrosis by variations in the size of the kidney on palpation. In tuberculous of the urinary organs the diagnosis is aided by the cystoscope and ureter catheter, with the examination of the urine for tubercle bacilli, which by careful searching can be found in almost all cases. Owing to the inconstancy of the cardinal symptoms of stone, x-ray examination is most valuable, since a stone shadow can be detected in 97 per cent. of the cases. The deepest shadow is produced by calcium carbonate stones, and then, in diminishing intensity, by oxalates, phosphates, and ammonium magnesium phosphates. The shadow is often not detected in calculi of uric acid, xanthin, and cystin. When a stone shadow is detected by the x rays, if it is to the median side of the kidney shadow the stone is extrarenal, in the kidney pelvis, and can be easily removed by incision of the kidney pelvis. If the stone shadow is within the kidney shadow the stone is in the kidney parenchyma or in an intrarenal kidney pelvis, and usually nephrotomy is necessary (with the risks of haemorrhage and secondary suppuration). Pyelography is of great service. A fluid which gives a shadow (10 to 15 per cent. solution of sodium bromide) is injected by the ureter catheter into the pelvis of the kidney. If the shadow of the stone is thereby obliterated the stone is in the pelvis of the kidney; if not obliterated, in the kidney parenchyma. The bad results following the use of collargol for pyelography can be avoided by the use of sodium bromide solution. Change in position and size of the kidney pelvis (as occurs in hydronephrosis) can be detected by pyelography. If no x-ray shadow of a stone can be detected it may be composed of uric acid, xanthin, or cystin. After washing out the kidney pelvis with collargol or sodium bromide solution every second day, such stones may give a shadow.

## 213. Haematoma of Rectus Abdominis.

J. BONNECAZE (*Paris Méd.*, August 25th, 1923, p. 145), who records a case in a man, aged 72, following an attack of influenza complicated by pulmonary congestion, states that haematoma of the rectus abdominis muscle may be either traumatic or spontaneous. Traumatic haematoma is liable to be met with in young soldiers, especially cavalrymen, owing to contusion of the muscle by the pommel of the saddle, or may be due to a violent blow, such as the kick of a horse. Spontaneous haematoma may occur in typhoid fever, as a rule in the third week, as the result of Zentor's degeneration, and is very liable to become infected, giving rise to an abscess in the abdominal wall. A retromuscular haematoma may occur in the course of pregnancy or after delivery. In a fair number of cases it may occur in an apparently healthy person, but as a rule there has been a recent history of influenza or pulmonary congestion, or the patients are the subjects of cirrhosis of the liver, gout, or chronic nephritis. The symptoms are pain (which may

be violent or slight, on the occasion of a muscular effort, a cough, or simply a movement in bed), swelling, and ecchymosis. The swelling is usually of moderate dimensions, but it may reach the size of a child's head and even fill the right half of the abdomen (Schumann). Ecchymoses have been noted in about half the cases, either in front of the muscle or at some distance from it. When the three symptoms—pain, swelling, and ecchymosis—are present together the diagnosis is usually easy, but sometimes the ecchymosis may be absent, the pain may simulate that of appendicitis, and the swelling may be mistaken for an ovarian cyst or a malignant growth. Treatment varies according to the size of the haematoma. When it is small there is no need to interfere, as there is a spontaneous tendency to resolution; but as soon as it attains a considerable size the tumour should be incised and the blood clots evacuated, since if left to itself a larger haematoma is liable to become infected on the slightest provocation, such as a boil or a scratch on the skin of the abdomen.

## 214. Torsion of the Testicle.

H. BARDY (*Finska Läkaresällskapets Handlingar*, July-August, 1923, p. 399) discusses this accident in connexion with two cases which occurred in his hospital within the same month. The signs and symptoms were practically identical in these cases, but he failed to diagnose the first case correctly because the clinical picture was in many and important points utterly different from the textbook accounts of this accident. In the first case, that of a workman, aged 23, there was a history of a sudden attack of violent pain in the abdomen, groin, and right testicle. The temperature and pulse were normal, but the patient was obviously collapsed. The right testicle, to which the patient referred all the pain, was tender but not enlarged. The right epididymis, on the other hand, was much enlarged, and it contained several hard nodules of varying size and great tenderness. The cord was neither swollen nor tender. Tuberculous epididymitis was diagnosed, and it was assumed that the sudden onset of pain and the great tenderness of the epididymis were due to compression of the testicle while the patient was at work. Several hours later the testicle as well as the epididymis was much swollen, and the scrotum was red and oedematous. In both cases an operation was performed under local anaesthesia, and a 360 degree twist of the cord was found just above the testicle, where the cord was furrowed as if it had been secured by a ligature. Above this point the cord was normal. Probably the testicle took longer to swell than the epididymis because the former is enclosed in the thick and inelastic walls of the tunica albuginea. The reflection of this membrane over the epididymis is thin and elastic, allowing the epididymis to swell and its veins to become distended. These veins formed the hard nodules felt in both the author's cases. Only at a comparatively late stage do the scrotum and testicle become oedematous and swollen. Of the 73 cases published before 1906 only 7 were at once correctly diagnosed, and in only 11 of the 73 cases was this accident suspected. The author insists that this accident can happen only in the presence of such congenital abnormalities as a patent tunica vaginalis or other abnormal condition in which the testicle hangs as freely as a plum from its stalk.

## Abscess of the Tongue.

215. E. DELANNOY (*Archiv. Internat. de Laryngol., Otol. et Rhinol.*, April, 1923, p. 418) states that though abscesses of the tongue are mentioned in the textbooks they are far from common. He records a case in a woman of 24 years who attended because she could not close the mouth. For three days she had a feeling of discomfort in the mouth followed by swelling of the tongue and intense pain which radiated towards the ears and neck, and which was made worse by swallowing. Finally, deglutition and mastication became impossible, and on examination the tongue was found to be so swollen that the mouth could not be closed. The lips could be nearly closed but not the jaws. The tongue was so enormous that it completely filled the mouth, the teeth being buried in its sides. It was white and tender, whilst the floor of the mouth and the pharynx were normal. The submaxillary glands were enlarged. A soft spot was found in the middle of the dorsum of the tongue. This was followed by an ounce of thick foul pus which ran out. It is often, as in this case, very rapid return to normal. It is often, as in this case, difficult to determine the cause of the abscess. Probably a small abrasion together with a diminished resistance of the particularly virulent organism account for it. The diagnosis must be made from that of abscess of the floor of the mouth which can push the tongue forwards and upwards. The soft fluctuating spot in a hard tongue finally clinches the diagnosis. In very early stages gargles and mouth wash should be used, but once suppuration has occurred incision must be employed.

function of the thyroid; in a case of severe myxoedema in a girl of 11 years the transplant was taken from a patient whose goitre had to be removed. A few weeks later the girl had developed between the peritoneum and fascia lata, where an apparently healthy piece of gland from the goitre patient had been transplanted, a hypertrophic goitre of the size of an apple, and at that time all her symptoms of myxoedema had disappeared; she was quite well for five years, when she had typhoid fever; the abdominal goitre became infected and an abscess formed which had to be opened; within a few weeks all her symptoms of myxoedema came back. Von Misesberg of Vienna a year ago published a similar case; the patient had been cured of myxoedema by transplanting a piece of gland of a goitre patient in the peritoneum below the liver. The patient died several years after the transplantation from pneumonia. At the post-mortem examination a hypertrophic goitre of the size of a hen's egg was found under the liver.

We have succeeded in demonstrating experimentally that the transplant is active. As a rule such experiments have been conducted in a way that could not give a result. The transplantation has usually been made into an animal with a normal thyroid gland; the organism had no want of thyroid and the graft did not live. We proceeded in a different way. We first removed the animal's thyroid almost totally, avoiding the parathyroids, and then waited until the animal developed characteristic symptoms of hypothyroidism. Then a piece of normal thyroid gland of a healthy animal of the same species was transplanted into the upper end of both thyroid bones. We then waited until the symptoms of myxoedema in the transplanted animal had disappeared, and a few months later removed the two pieces of gland from the bones, and within a few weeks the symptoms of myxoedema reappeared. I believe that by these observations and experiments we have proved that the transplant can live and, in view of our clinical results, recommend this as the method of choice in cases of hypothyroidism. We believe that it should be tried also in cases of total absence of the thyroid gland.

#### Selection of Transplant.

The method of performing transplantation in our cases was that described by my father Theodor Kocher in 1909. There are three types of transplantation that can be employed; we may take (1) a normal gland of an animal; (2) pieces of a goitre from a case of Graves's disease; (3) the hypertrophic thyroid tissue around a nodular goitre. We have used all three methods. As early as 1908 we used some heterotransplants from sheep and goats. The best glands to transplant are those from pregnant animals. This method has given a good result in some cases. One of the cases of congenital total absence of thyroid gland mentioned above was entirely cured by transplantation of two pieces of the size of a cherry of a normal thyroid gland of a pregnant sheep into the two thyroid bones. As a rule, however, homotransplants are much better. They are best taken from the hypertrophic gland of a severe but recent case of Graves's disease, which is in a condition of exuberant cellular hypertrophy and active new formation of vesicles. The best part of the gland to be taken is the upper pole or posterior part of the gland near the superior thyroid artery. It is essential that the pieces of gland (we take usually two to four pieces of the size of a small cherry) shall be put into the receiver's body immediately after being cut out of the donor. The receiver must be ready on a table next to the donor, and the bed for the transplant must be carefully prepared before-hand and in particular all haemorrhage carefully stopped. Besides the glands of patients with Graves's disease, we have very often taken pieces of the hypertrophic thyroid tissue around goitre nodules in young healthy goitre patients. Of course, in every case the donor is examined very carefully beforehand; tests for syphilis and tuberculosis must more especially be done.

#### The Operation.

As mentioned above, we transplanted mostly into the upper end of the tibial bone, where, with Doyen's trephine, the corticalis is opened and a bed in the bone marrow made, exactly of the size of the transplanted piece. We have chosen this bone, first, because it is very vascular and has a

so well-lying universal fact that they cannot be held to be solely frequently, if not always, present, but these conditions are general resistance. Pyrexia and dental caries are particular group of cases except in so far as they lower the these extra-digestive fact are of any real importance in this factors of infection, but we are very doubtful whether tions, pyelitis, otitis media, furunculosis, etc., as the instances as the starting point of the attack.

Certain observers have cited cervical and uterine infection of digestive and metabolic processes are recorded in many of the body are liable to inflammatory changes after this lowering of resistance, though serous membranes in all parts predisposing cause, probably acting simply by the general attacked by other infective agencies. Influenza is another joint circulation that the synovial membrane is liable to be and may cause such laxity of ligaments and impairment of disease, though repeated inflammatory reactions do occur this condition does not produce chronic intra-articular incidence of this disease in the general population. But to occur more frequently than can be accounted for by the give a history of previous debilitating disease or some prolonged physical strain. A history of rheumatic fever seems Patients suffering from rheumatoid arthritis frequently

#### Etiology.

enlargement. alteration of the normal blood picture, and with glandular with digestive disturbance, upset of general metabolism, structures in intimate relationship to joints, and associated with periodical exacerbations, but occasionally acute in its onset and manifestations, leading to serious deformity of usually running a prolonged subacute or chronic course, insidious origin, affecting young adults in particular, We would define rheumatoid arthritis as a disease of preliminary investigations for the furtherance of this object. arthritis from this group, and it is our purpose to report our have been made to differentiate so-called true rheumatoid arthritis, "or" "indefinite arthritis." Several attempts of "multiple non-specific infective arthritis," "focal however, with this and have preferred the more vague terms, "those with experience in this class of case are not satisfied," been aggregated under the term "rheumatoid arthritis," number of cases of non-specific origin which in the past have panmyelocytosis, gonococcus, etc. But there remains a large specific infective agencies such as the tubercle bacillus, the material by the recognition of special types as being due to in the classification of this amorphous group of clinical process, and a certain degree of progress has been made in the etiology of the arthritides is some form of infective Art authorities are now agreed that an important factor

### DIFFERENTIAL DIAGNOSIS OF RHEUMATOID ARTHRITIS AS A CLINICAL ENTITY.

PHYSICIANS TO THE ROYAL INFIRMARY WATER HOSPITAL, BATH.

cases. In 13 cases of severe climacteric disturbances, such as headaches, nervousness, etc., the symptoms were either cured or ameliorated within a few days of treatment. The author states that the results are due to the stimulation of the pituitary causing further stimulation of the genital organs. The treatment is stated to be free from danger or discomfort of any sort. With the larger doses used by Hotbauer slight headaches sometimes occurred and the hair was liable to come out where the x rays had been applied, this being followed after a short interval by luxuriant growth of hair all over the head. The author concludes by stating that the signs and symptoms, such as cessation of growth, glycosuria, etc., which are supposed to be due to pituitary deficiency, are not cured by the administration of pituitary extract, and he therefore affirms that these symptoms are due to some degeneration of the brain near the pituitary body.

#### 221. Radiography of Closed Fallopian Tubes.

W. T. KENNEDY (*Amer. Journ. of Obstet. and Gynecol.*, July, 1923, p. 12), in patients in whom complete or partial occlusion of the Fallopian tubes has been demonstrated by Rubin's method of gaseous insufflation of the uterus or tubes, locates the site of occlusion by radiographic examination after filling the same organs with a 20 per cent. solution of sodium bromide under pressure. Tubal occlusion at the uterine cornu or the isthmus is indicated by failure of the tube to cast a shadow; if the tube cast a shadow the presence of a shadow in that isthmus is taken to indicate that the tube cannot contract enough to empty its contents; and the absence of a shadow in the isthmus points to ability of the tube to empty its contents in either direction. If one tube only is open practically all the sodium bromide is seen at the corresponding side of the pelvis. In 26 patients 30 per cent. of the tubes examined were found to be occluded at the isthmus and 69.2 per cent. at the fimbrial region; in the latter group, provided the husband is normal, there is, according to the author, some prospect of success after salpingostomy in sterile patients.

#### 222. Determination of Tubal Patency.

A. H. ALDRIDGE (*Amer. Journ. of Obstet. and Gynecol.*, July, 1923, p. 53) describes a study of 600 patients in whom the patency of the Fallopian tubes was determined by Rubin's method of insufflation of the uterus and Fallopian tubes by carbon dioxide. If gas passed into the abdomen at an intra-uterine pressure below 150 mm. of mercury the tubes were considered patent; if a pressure of 150 mm. or more was required they were classed as partially occluded; manometer readings of 200 mm. at repeated trials were taken to indicate occlusion. It was found that routine fluoroscopic examination was not necessary to determine the passage of gas into the abdomen; a drop in intrauterine pressure, combined with the onset of pain in one or both of the patient's shoulders, constituted a sufficiently accurate sign. Aldridge finds that the Rubin method is a simple and safe diagnostic procedure, provided that the patients are not examined when near a menstrual period or in the presence of acute pelvic inflammatory disease or serious cardiopathy; by this technique a certain number of cases of complete or partial occlusion are determinable which are not apparent to inspection at operation. There is little evidence that insufflation has any curative value in cases of sterility, and even after operative opening of a tube or tubes in cases in which both tubes have been involved in an inflammatory process sterility continues in a very high percentage of cases so that the value of the Rubin method is chiefly diagnostic. In 236 cases of primary sterility partial or complete tubal occlusion was found in 66 per cent., and in 119 cases of secondary sterility in 52 per cent. More than one-fifth of the patients showed tubal occlusion in spite of negative findings by bimanual examination.

#### 223. Quinine Treatment of Pregnant Malarial Patients.

P. CASTAGNA (*Rivista di Ostetricia e Gynecologia Pratica*, June, 1923, p. 268) has not been able to confirm in his experience the findings of those observers who have recorded a large incidence of abortions and premature labours after administration of quinine to pregnant patients suffering from malaria. Thirty-seven pregnant women were given doses of 0.25 to 0.5 gram by the mouth, and none exhibited any untoward effect; nineteen were in the third month of gestation, and thirty-two in the seventh to ninth months. Twenty received doses of 0.5 to 1 gram given subcutaneously; abortion was threatened (but did not occur) in one of these patients who was three months pregnant, and premature labour followed in two patients who were in the eighth and ninth months respectively. In the two last cases the occurrence of premature labour was possibly attributable to malarial hyperpyrexia.

## Pathology.

#### 224. Insulin in Tissues other than the Pancreas.

C. H. BEST and D. A. SCOTT, Toronto (*Ann. Roy. Soc. Med.*, August 4th, 1923, p. 382), have been able to prepare active extracts from the submaxillary, thymus, and parathyroid glands, and from liver, spleen, and muscle tissue. These extracts have been repeatedly tested on normal rabbits, and have consistently produced a marked lowering of the blood sugar of these animals. A large dose produced typical insulin convulsions in the rabbits. The convulsions were alleviated by the administration of dextrose. The amount of insulin obtainable from 1 kg. of thymus or submaxillary gland tissue exceeds that originally obtained from pancreatic tissue. This yield is, however, only a small fraction of that obtainable when pancreatic tissue is treated by the present process. The authors have secured results which tend to indicate that this substance, which they believe to be insulin, is present in somewhat greater amounts by pregnant women than in normal men. Insulin, they state, is present in every tissue they have investigated.

#### 225. Tests of the Cerebro-spinal Fluid.

H. D. WRIGHT and W. O. KERMACK (*Edin. Med. J.*, August, 1923, p. 365), after investigating the relative values and uses of the colloidal benzoin and colloidal gold tests of the cerebro-spinal fluid, conclude that the interpretation of results is not perfectly straightforward, and that it is justifiable to consider any particular curve as diagnostic of a definite disease. Of the two the gold test seems to be more delicate, though its results are very faithfully reproduced in the benzoin test. Although precipitation in some of the first five tubes of the benzoin test strongly suggests syphilitic nervous lesion, the more marked the precipitation being the more suggestive of an active process, this should be relied upon too exclusively since tuberculous meningitis and disseminated sclerosis may give similar precipitation. For this reason the test should not replace the Wassermann test, but should rather be used as an adjunct to it. The widening of the normal zone of precipitation should be in direct relation to an increased precipitation in the butyric acid test, being most marked in cases of meningitis and since such extension of the zone is usually a feature of epidemic encephalitis this may assist in distinguishing from early meningitis. In general paralysis the colloidal benzoin test may afford a measure of the activity of the disease if studied in a series of cases over a long period. Similar considerations apply to the gold test, but while helpful in arriving at a conclusion, do not possess an exaggerated value sometimes claimed for them.

#### 226. Bowen's Disease.

J. H. BROERS (*Nederl. Tijdschr. v. Geneesk.*, June 21st, 1923, p. 2805), who records a personal case, states that J. T. Bowen of Boston described two cases of a skin disease which, after careful clinical and histological examination, he grouped among the precancerous diseases of the skin. These include xeroderma pigmentosum, keratosis arsenicalis, actinic keratosis, chronic x-ray dermatitis, keratoma scutellum, Paget's disease of the nipple, tar keratosis, chimney-sweeps' cancer, etc. The disease may be regarded as an epitheliomatosis of a chronic eczema. It occurs in men and women of middle age on any part of the skin, but has an extremely chronic course—in Broers's case already been in existence for twenty-two years, having had no injurious effect upon the patient's health, so that the prognosis, though unfavourable as regards cure, is good as regards duration of life.

#### 227. Blood Changes in Small-pox.

W. H. HOFFMANN (*Munch. med. Woch.*, August 10th, 1923, p. 1052) points out that, whilst the clinical features of small-pox are characteristic in severe epidemics, the diagnosis is always easy in mild epidemics, especially in the early stages. Hence we have need for additional aids to diagnosis in an epidemic of small-pox in Havana (Cuba) the author has made 300 blood examinations. He believes the results to be of diagnostic value. These blood changes are recorded in detail. The author concludes that in small-pox blood changes occur regularly which are peculiar to the disease; especially great increase of the leucocytes, beginning on the fourth day of the illness, relatively marked lymphocytosis, high degree of eosinophilia, presence of myelocytes, first high Arnetz index (based on the number of myelocytes in the polynuclear cells). Specially characteristic is the occurrence of myelocytes. A similar blood picture occurs only in varicella, in which, however, the total count of leucocytes is generally rather diminished, and the exception of occasional slight increase about the tenth day of the disease.

depends on the relative production of a haemolysin or a  
 invarioxin. We would suggest a similar genesis in many  
 instances of rheumatoid arthritis by means of a toxin with a  
 special affinity for synovial membrane.  
 However, it must always be remembered that the whole  
 metabolism is upset, and further work is required to inves-  
 tigate other possible factors responsible for the production  
 of the clinical changes observed. Many observers have  
 assigned importance to the isolation of various strains of  
 streptococci from the stools, but the results are so far very  
 variable and no reliable conclusions can be drawn. It is  
 possible that the factor of acholurhythmia may have some  
 influence in determining this state of affairs, in view of the  
 work of Billings<sup>1</sup> and his collaborators on the variability of  
 streptococcal strains in different media.  
 We wish to thank Dr. Munro, pathologist at the Royal Mineral  
 Water Hospital, Bath, who was responsible for the blood counts and  
 gastric analyses mentioned above.

### A LARGE RENAL CALCULUS.

R. OGIER WARD, M.C., OXON., F.R.C.S. (ENG.),  
 ASSISTANT SURGEON TO ST. PETER'S HOSPITAL; VISIT ASSISTANT,  
 SURGICAL UNIT, ST. BARTHOLOMEW'S HOSPITAL.

Large stones of the kidney are not common; in this case the calculus weighed 1 lb. 3½ oz., and it is of interest that the symptoms were very mild and that operative treatment was successful.  
 The drawings by Mr. Thornton Shells show well the shape of the calculus (Fig. 1) and the left kidney removed with it (Fig. 2). The main mass of the calculus lay in the dilated renal pelvis; the short branches occupied five of the much damaged calyces. The outlet from the renal pelvis is small, and below that the ureter is seen to be greatly dilated and its wall thickened. The small calculus partially blocked the left ureter at its lower end close to the bladder.

FIG. 1.—Calculus.  
 FIG. 2.—Kidney with dilated pelvis.  
 Dr. H. R. Archer has kindly analysed the calculi and reports as follows:

*Renal Calculus*.—Weight 1 lb. 3½ oz. (555 grams). Samples taken at five points between the external surface and the centre show a composition, almost constant, of ammonium magnesium phosphate and a little calcium phosphate. The superficial layers also contain a little calcium carbonate. The branches consist of ammonium magnesium phosphate. *Ureteric Calculus*.—Weight 28 grams. The composition is similar.

The patient was a man, aged 58, who was under my care at St. Peter's Hospital. From youth until he was 35 years old he was in the merchant service, then he retired and lived in Dorchester. For the last twenty-three years his urine has always been dark, sometimes as dark as port, and occasionally in clots. For the last five years he had occasionally had pain in the left groin but never any renal or vesical pain. For two years he had occasionally had urine that had passed clots of blood. On examination the left kidney was easily palpable and obviously greatly enlarged and a little tender. It was freely moved in one or two directions. There was no family history of stone. His previous health had been excellent, except for malaria when 21 years old, and acute appendicitis requiring operation five years ago, and frequency of micturition, with fever and rigors. There was no history of stone. His previous health had been excellent, except for malaria when 21 years old, and acute appendicitis requiring operation five years ago, and frequency of micturition, with fever and rigors. There was no history of stone. His previous health had been excellent, except for malaria when 21 years old, and acute appendicitis requiring operation five years ago, and frequency of micturition, with fever and rigors.

### TREATMENT OF URTICARIA WITH COLLOSOI

In a large skin clinic a considerable percentage of cases of urticaria, which are most intractable to treatment, are means definitely understood. I think we may reasonably assume that it is due to the action of an irritant on the vessels at the point where the cutaneous lesions make their appearance. This irritant, be it a toxin or protein, may reach the vessels from an external source or from the blood stream. As an illustration of the former I may cite the urticarial rash caused by netles; the rash in this case is produced by an irritant from the plant reaching the blood and lymphatic vessels through the skin. As an example of the latter, the urticaria following the ingestion of certain shellfish may be taken; here the toxin or protein would appear to reach the blood stream through the intestinal canal.

It is the experience of every dermatologist that often cases are met with for which no cause can be assigned. It was owing to this experience that I was induced to try collosoi manganese in the treatment of urticaria. Manganese given in a colloidal state increases oxidation and stimulates the dispersion of these particles so that the surface exposed to the invading particles becomes greater. The increased activity of the protein particles in the tissue and fluid has a destructive action on the invading protein or toxin. It was with this theory in mind that I decided to try collosoi manganese in some obscure cases of urticaria. The following four cases are given to illustrate the effect.

A woman, aged 27, unmarried, had suffered from daily attacks of "nettle rash" for twelve months. When I first saw her (the face, arms, legs, chest, and neck were thickly covered with dark wheals varying in size from a coffee bean to a three-shilling piece). There was intense itching and burning. I gave her 0.5 c.c.m. collosoi manganese by intramuscular injections. On returning at the end of a week she reported that the rash had been much better and the burning and itching sensation decidedly diminished. I gave another 0.5 c.c.m., and the again reported an improvement at the end of the second week. I gave her four more injections (1 c.c.m., 1.5 c.c.m., and 2 c.c.m.) at weekly intervals, and at the end of six weeks of treatment she was quite free of her trouble. Six months afterwards she had a slight recurrence, and

These two large series agree fairly closely, the main difference being the interchange of the positions of the rectum and splenic flexure respectively.

*Analysis according to situation in the right or left half of the colon* shows that only 13.29 per cent. of the growths causing obstruction were on the right side, as against 86.7 per cent. on the left; that is to say, there is a 6.5 to 1 chance of a malignant growth that has caused acute colonic obstruction being found on the left side—a fact not without its importance in relation to operative treatment.

TABLE IV.—Operations Performed for Acute Colonic Obstruction (Excluding Intussusception), with Results.

*Primary Resection.*—It must be laid down as a basic principle of the treatment of acute obstruction of the colon that resection with immediate restoration of continuity (that is, without drainage of the proximal bowel) is an unjustifiable procedure. In this series it was performed 9 times with 3 recoveries (2 of caecum, 1 of sigmoid) and 6 deaths (1 of transverse colon, 1 of splenic flexure, and 4 of sigmoid)—a mortality of 66.6 per cent., which is almost double the average mortality of the whole series. It is the experience of most surgeons that whereas primary resection with immediate union can be successfully carried out in the small intestine, and is there, in fact, the operation of choice, the same procedure proves disastrous in the colon. This difference is accounted for by the much greater freedom with which resection can be carried out in the small gut, so that it is always possible to secure a fairly healthy bowel at the site of union and to bring the ends together without tension; moreover, the contents of the ileum are more fluid, move along more rapidly, and are less septic than those of the colon. On the other hand, the consequences of establishing an artificial anus in the small intestine are more serious than in the colon, and nutrition may be greatly impaired when the fistula is placed (and it is often impossible to know its exact location) well away from the ileo-caecal valve. In the ileo-caecal region the conditions approximate to those obtaining in the small bowel, and this is the only region of the colon in which primary resection followed by immediate anastomosis has any claim whatever to consideration. In the Manchester Royal Infirmary series two of the three successful cases concerned the

ileo-caecal region; excluding the caecum, the mortality for the rest of the colon is 85.7 per cent. Whenever resection of the colon is essential, as in gangrene from volvulus or internal strangulation, it must be combined with drainage of each end of the bowel, preferably by tying in a Paul's tube; at a later operation continuity may be restored. This "two-stage" operation, associated with Paul and with Mikulicz, is sometimes advocated in acute colonic obstruction from malignant growth: The bowel concerned is mobilized, its mesentery divided between ligatures, the whole coil brought outside the abdominal wound, which is then sutured closely around its two limbs, and a Paul's tube is fixed into each limb; either at the time or a few days later the coil is cut away; still later, continuity is restored either by the use of the enterotomy to divide the "spur," or by direct suture. This operation should, in my opinion, be restricted to cases where the colon is gangrenous; as applied to malignant growth it has the very strong objection that in the presence of obstruction the removal of the lymphatic area in the mesentery is very likely to be insufficiently carried out. It is far better to content oneself with a caecostomy for the immediate relief of the obstruction and to follow this up later by a leisurely and thorough excision of the bowel and its corresponding lymphatic area along the lines so excellently laid down in the work of Jamieson and Dobson.

*Lateral anastomosis* was performed in 11 cases, with 3 deaths—mortality 27.7 per cent.; there were 5 ileo-colostomies (with 2 deaths), 2 caeco-colostomies (both recovered), and 4 colo-colostomies (3 of the transverse colon to the sigmoid, all of which recovered, and 1 of the descending colon to the sigmoid, followed by death). In all these cases a preliminary laparotomy had disclosed an inoperable malignant growth and the palliative anastomosis was the alternative to colostomy. Ileo-colostomy for obstruction from growth of the colon, carried out in cases where, as usually obtains, the ileo-caecal valve is competent to prevent the regurgitation of caecal contents into the ileum, entails, as was pointed out many years ago by Professor Rutherford Morison, a serious risk of later gangrene or perforation of the caecum; this is due to the tension caused by the gradual accumulation of intestinal secretions pent up between the ileo-caecal valve and the growth. Caeco-colostomy is the correct procedure in these circumstances, and if ileo-colostomy be performed it must be combined with either appendicostomy or caecostomy to prevent such tension. I have used ileo-colostomy for the immediate relief of obstruction shown at exploratory laparotomy to be due to an operable carcinoma of the transverse colon near the splenic flexure; later the whole of the gut between the sites of anastomosis in the ileum and sigmoid, together with its mesentery, was successfully excised, the ends of the bowel being simply crushed, ligatured, and invaginated by purse-string suture.

I propose to approach the discussion of the appropriate treatment of acute obstruction of the colon mainly from the clinical standpoint and to consider the cases as they present themselves prior to the operation under three groups:

*Group I.*—Where we cannot tell whether the obstruction is in the ileum or the colon.

*Group II.*—Where we can locate the obstruction to the colon, but its situation therein is not known.

*Group III.*—Where the site of obstruction in the colon can be definitely ascertained.

#### GROUP I.

The size of this group should steadily diminish as experience increases, and with a reasonable amount of time expended upon a careful physical examination of the abdomen I believe the diagnosis between small and large intestine obstruction is possible in the majority of cases. As regards their relative frequency, the colon was concerned in 28.48 per cent. of all cases of acute intestinal obstruction in the Manchester Royal Infirmary series, but if we exclude the two groups of strangulated external hernia and intussusception, both of which are readily recognized—the former by the palpable swelling at a hernial orifice, the latter by its age of incidence and its very characteristic

STURGERY OF THE BILIRY PASSAGES.

PROFESSOR HARTMANN has written a treatise on the surgery of the biliary passages, which, while it embraces the whole of that subject, is devoted more especially to the various forms of cholecystitis and their complications. Although the work is principally based on his own personal observations, but the pathological anatomy of cholecystitis is described by Dr. Kennard and illustrated by him on a series of thirty-four well executed plates. Professor Hartmann's description of the technique of the various operations practised on the biliary passages is followed by an account of the results, and more particularly of the remote results, of the operations. In discussing the pathology of biliary lithiasis he expresses the view that the cholesterinaemia, which is almost habitual in patients, is the result rather than the cause of the cholecystitis, and notes that the so-called strawberry gall bladder, in which the mucous membrane is studded with minute particles of cholesterol, is not generally associated with gall stones. Reference is made to Aligout's researches, in which it was shown that neither the presence of foreign bodies, nor biliary stasis, nor infection, would, acting alone, lead to the production of gall stones, but that their experimental production followed the action of an attenuated infection combined with partial stagnation of bile. In connection with calculi in the common duct, jaundice, it is stated, is never completely absent, but in 5 per cent. of the cases it had disappeared at the time of operation, although gall stones, some of large size, were found in the lower part of the duct, an observation that should lead the surgeon invariably to examine the common duct in all operations in biliary cases. Hartmann's statistics confirm the law of Controulet-Fertier relating to the dispersion of the gall bladder, but the value of the law is diminished by the fact that the enlargement of the liver in biliary obstruction often renders even a large gall bladder inaccessible to palpation. The propagation of inflammation to the peritoneum in cholecystitis differs from that in appendicitis in being less diffuse. In three cases only did Hartmann meet with a diffuse suppurative peritonitis resulting from cholecystitis. In the comparatively rare cases of acute peritonitis following perforation, it is recommended to drain the peritoneum by a tube in the pouch of Douglas, after dealing with the local lesion.

A chapter on the experimental results of ablation of the gall bladder is contributed by Dr. Hauserfort. The experiments described show that when a ligature is placed at a little distance from the termination of the cystic duct it is placed at the very termination of the duct no diverticulum results. In either case the main ducts undergo a compensatory enlargement, which, however, does not so far affect the intrabiliary ducts.

In the chapter dealing with operative technique the value of hypereztension of the trunk in obtaining a full view of the field of operation is insisted on. The reason why some operators have failed to appreciate the advantage of this position is that they have placed the block too far down in the lumbar region; it should be beneath the lower dorsal region. With hypereztension properly applied, combined with externalization of the edge of the incision, and retraction of the skin, so that in thin subjects the surgeon could, if he wished, secure the common duct to the edges of the abdominal incision. On the question of combining hypereztension with choledecomy Hartmann states that he performs the double operation in 65 per cent. of his cases. In speaking of the results of cholecystectomy reference is made to the frequency of incomplete removal of the calculi, and the consequent tendency to abandon this operation in favour of choledecomy.

A chapter is devoted to cancer of the bile-papilla, which

*Chirurgie des Voies Biliaires*, by Henri Hartmann. Paris: Masson et Cie, 1925 (Imp. des pp. 566; 37 figures, 27. 50 francs).

1. The first of these is the fact that the Commission has not yet received any information from the Government of the Republic of the Congo regarding the situation in the country.

MEDICAL, SURGICAL, OBSTETRICAL.

M. G., aged 22 years, was admitted to the Cranberry Sanatorium, Kingsmead, in July, 1927, as an acute case of pulmonary tuberculosis affecting the left upper and middle lobes, with a good deal of systemic intoxication. Her brother was already an in-patient with a similar lesion and systemic disturbance. During the first year a steady improvement was maintained, but in July, 1922, after an influenza cold the patient began to go back. She was kept in bed on complete rest, but in spite of this, a new focus began to appear in the left lower lobe. Within a few months a large cavity (containing by x-rays) had developed. The temperature was now 37.2, the sputum was now 50% per diem and the weight had fallen by 13 lb. (5.9 kg.).

After consultation it was decided to induce an artificial pneumothorax on the left side and this was begun on May 11th. On May 22nd, after three inductions of from 200 to 300 c.c.m. of air, the x rays showed the left lung fairly well compressed, no displacement of the mediastinum, a broad pleural effusion in the lower axilla and a slight amount of pleural effusion. A week later the effusion had reached the level of the fifth rib and the pneumothorax was registered as a respiratory distress at + 4, zero, steadily due to the spontaneous reabsorption of the gas which left the lung without any replacement of the level of the third rib and remained there, as was demonstrated from time to time during the following weeks.

By July 16th the pleural effusion was beginning to be absorbed and it was decided to go on with further inductions of air. The spodium had slightly increased. Before a refill was given, there was a sudden increase of spodium, very fluid, and obviously containing pleural effusion. This continued for forty-eight hours; the patient was evidently suffering from shock, and physical examination showed the dullness of the effusion replaced by a hyper-resonant note. The presence of a natural pneumothorax was proved by the induction of 500 ccm. of air without any alteration in the intrapleural pressure, which stood at zero. - 4. The was freely stimulated, but died in the early hours of July 22nd.

A post-mortem examination was unobtainable, but it seems evident that the continued stretching of the pleural cavity combined with the extension of the disease finally ruptured a paraseptal cyst, allowing the pleural effusion to be expected. The question arises: Would it have been better to remove the effusion in the first instance and replace with air?

I have to thank Dr. Felix Savy for permission to publish particulars of the case.

PHILLIS FLEMING, M.A., M.B., Ch.B.,

Sanatorium, Kingston, N.B.

ENTRUST POSITION OF CHILD DURING DELIVERY.

I was called to attend a puerperal confinement case, and on arrival found labour so far advanced that the vulva was gaping with each pain. On palpation I diagnosed face to pubes and did not make a vaginal examination. I waited for about five hours, but

mother and I were not prepared to do so, and she might have hurt herself, but there was her own convenience to consider. I left her to get something which I had put on a table, and intended to put the forceps on it, but she was not ready to do so, and I was not ready to come through, and I left it to nature. The head came through, although the chest and abdomen came through in the anterior position. I believe that if I had used the forceps I should have fractured the child's neck.

W. F. MOORE, M.B.  
KINGSBURY, TAMWORTH

degrees of obstruction, where there may be merely a temporary plugging of the lumen of the growth by a faecal mass, or a transient oedema of its wall, and where evidences of toxic absorption are wanting, there is a reasonable chance that with repeated enemata, etc., the obstruction may pass away, allowing a radical exploration to be made at a later date. The danger of thus temporizing is that of gangrene and perforation of the caecum, this portion of the colon being most affected by the increased intestinal tension quite irrespective of the site of the obstruction. Any localized tenderness over the caecum is, therefore, a strong contraindication to temporizing and demands operative relief of the obstruction.

Between these two extremes comes the largest class, where, although there is definite colonic obstruction, the general condition of the patient is not so grave but that there is a reasonable prospect of his being able to withstand a paramedian exploration to ascertain the site and nature of the obstruction; the question we have to decide is whether in these cases we should commence the operation with a paramedian exploration or content ourselves with a "blind" caecostomy. The advantages of the latter are: (1) It can be performed rapidly, under local anaesthesia, and with the minimum of shock—certainly very much less than that necessitated by a preliminary exploratory laparotomy followed by caecostomy or colostomy. (2) There is no interference with the growth and no new adhesions are formed. (3) The caecostomy opening is as far removed from the area of any further operation as any artificial anus can ever be. (4) It forms a good safety valve during any subsequent operation of resection, giving rest to the sutured bowel and minimizing the risk of leakage at the line of suture. (5) When not further required it often closes spontaneously on leaving out the tube—particularly if performed by one of the valvular methods—and in any case can be very readily closed by suture, with repair of the abdominal wall. On the other hand, an exploration sufficient to locate the obstruction, to disclose its nature, and to enable one to form an opinion of any value as to its operability in the future is always a difficult procedure in a distended abdomen—coils are liable to escape and may be hard to replace, and in the process of doing so the bowel wall may split. This risk may certainly be lessened by plunging a trocar into the caecum immediately it presents and allowing sufficient gas to escape to relieve tension; but this expends time and must increase the shock to a patient already toxæmic. Moreover, the site and nature of the obstruction are not always discovered—I have known a growth of the splenic flexure in an obese patient to be entirely overlooked—so that the caecostomy which is then performed is still "blind," and the patient has gained no advantage to compensate for the increased risks of the preliminary exploration.

To my mind, the strongest argument that can be urged against "blind" caecostomy is the fear that one may be leaving unrelieved a portion of bowel with its circulation obstructed—volvulus or internal strangulation—so that although death from acute ileus is averted, perforative peritonitis will later inevitably result. What are the chances of this happening? In the Manchester Royal Infirmary statistics, of 199 cases of acute colonic obstruction 24 owned some cause other than growth; of these, 9 were strangulated external hernia and would not be overlooked; 2 cases of ileo-caecal tuberculosis and 1 of sigmoid diverticulitis involved no risk to the circulation; of the 5 cases of volvulus the 2 involving the caecum would have been recognized on exposing the caecum; 2 of the 3 cases of recognized on exposing the caecum; 2 of the 3 cases of volvulus of the sigmoid were not suspected prior to operation and might have been missed; of the 7 cases of adhesions, in 1 only was there definite strangulation of bowel. Thus "blind" caecostomy might, at the most, have resulted in overlooking gangrenous intestine in 3 out of 199 cases, or 1.5 per cent. I think even the most optimistic advocate of preliminary exploratory laparotomy, necessitating, as it does, a general (or spinal) anaesthetic, must admit that it would add more than 1.5 per cent. to the mortality.

The advantage usually urged in favour of preliminary exploration is that valuable information is thereby obtained as to the site and nature of the obstruction, and, if it is a growth, as to its local fixity, the extent of glandular involvement, and the presence of secondary deposits—all of which remain an unknown quantity with "blind" caecostomy. Even when obtained, however, this knowledge is seldom acted upon at the time—it is for future guidance. Now, admitting that such knowledge is not only highly desirable but absolutely essential before the final disposition of the case can be decided, why seek to obtain that which it is not immediately necessary to possess, at a time when the patient is in the throes of acute obstruction? Surely it is far better acquired when caecostomy has caused all urgency to pass away, when the abdomen has become flaccid, and when the site of the obstruction can often be determined beforehand by a careful physical examination, by sigmoidoscopy, or by radiography after a barium enema. Even if it is still undetermined before the second operation, there is a 6.5 to 1 chance of its being on the left side, so that a left paramedian incision will give safely all the information desired, and can be immediately followed by the requisite therapeutic measure—resection, short-circuiting, or artificial anus elsewhere than the caecum. Should it prove that such can be better performed through some other incision, the left paramedian incision can be readily closed and a fresh one adopted.

It may be argued that the information acquired at a preliminary exploration may be such as to there and then negative any future surgical treatment, and so save the patient a second and unnecessary operation, such as he would certainly be submitted to after recovery from a "blind" caecostomy. For instance, it might be considered that the extent of local fixation or the presence of metastases would prevent future resection. I have already referred to the impossibility of deciding the degree of local fixity unless the parts are actually freely exposed. Even metastases do not necessarily negative all further operation—a short-circuit or a "palliative" resection may allow of closure of the caecostomy and the avoidance of an artificial anus, with all its drawbacks, if not for the remainder of life, at any rate for many months. Practically, it is only where an inoperable growth is found to be too low down in the sigmoid for short-circuit to be feasible later that a preliminary exploration, followed, as it would be in this event, by a sigmoidostomy above the growth, would complete all operative procedures at one sitting.

Weighing the arguments for and against, I feel strongly convinced that when, in any given case of acute intestinal obstruction, the site of obstruction can be located to the colon but is not more precisely known, and where there is no special reason to suspect volvulus or internal strangulation, "blind" caecostomy should be performed as the sole immediate procedure.

### GROUP III.

Here the actual situation of the colonic obstruction is known: (a) usually because a growth has been discovered on rectal examination; (b) in others there is a palpable abdominal tumour; (c) very exceptionally obstruction has supervened very shortly after a sigmoidoscopic or a radioscopic investigation has disclosed its site.

(a) If rectal examination enables us at once to decide that the growth is definitely inoperable on account of local fixation to the bladder, prostate, uterus, or sacrum, the correct procedure is left inguinal colostomy (sigmoidostomy), since with a growth placed so low a future palliative short-circuit is impracticable. Should rectal palpation not contraindicate a future radical operation, I prefer laparotomy through a left paramedian incision of just sufficient extent to permit of manual examination of the sufficient extent to permit of manual examination of the extent and fixity of the growth, the degree of glandular infection, and the presence of metastases in the liver and peritoneum; the operation is concluded by fixing a loop of the sigmoid into the wound and opening it either at once, tying in a Paul's tube, or a few hours later, according to

held by the author to be due to intermittent activity of the liver in either storing up sugar as glycogen or discharging the latter as glucose into the blood stream according to the condition and demands of the organism.

The second section is concerned with the rise in the quantity of sugar in the blood after administration of glucose. In normal individuals the upper limit to which the blood sugar can be raised is about 0.18 per cent., while in diabetics the total rise of the curve is directly proportional to the amount of glucose ingested. The opinion is expressed that the production of enzymes or hormones (insulin) is stimulated by the presence of large amounts of sugar, and that this increased activity in the normal organism prevents the rise of blood sugar above the value of 0.18 per cent. The measure of this enzymatic activity is called the "removal acceleration," and it is shown that in diabetics this power is lower than normal in degrees varying in proportion to the severity of the disease. Moreover, the rise of the blood sugar curve per gram of glucose taken is, under proper conditions, constant in diabetic subjects, and a function test based on determination of the "one gram rise" and "removal acceleration" is proposed.

The third section deals with the distribution of glucose between plasma and corpuscles. In fasting diabetics there is usually a higher percentage of sugar in the plasma than in the corpuscles, while in normal blood the percentage in each is about equal. This may of course be due simply to the concentration of acids, as Hamburger has shown that in horse's blood the cells give up glucose to the plasma when carbon dioxide is passed through it.

The method for determination of blood sugar used throughout these researches is that of Hagedorn and Jensen. It is based on the reduction of potassium ferricyanide. It appears to be a convenient, easy, and accurate procedure, and, as it requires only 0.1 c.cm. blood, is worthy of note and trial. A description of the method is given in *Biochemische Zeitschrift*, 155, 46 (1923).

The book is printed in English, and although the phraseology is occasionally somewhat unusual and there are frequent misspellings, the meaning is always clear. The book is designed for the general practitioner and consequently the bedside features of the various heart affections are presented rather than the aspects which are determined by instrumental aids.

The main features of the book are probably well known. After dealing in a general manner with heart failure, chapters are devoted to certain symptoms and some of the physical signs met with in patients suffering from heart disease. Particular attention is given to murmurs and the differentiation between physiological, functional, and organic murmurs. A consideration of heart irregularities leads to separate chapters on auricular fibrillation and atrial flutter. A useful though short part deals with so-called "heart attacks." Prognosis and treatment appear at various parts of the book, but the principles of both are summarized in the closing chapters. An essay on medical research, with which the previous edition opened, has been relegated to an appendix.

The practice of printing many of the salient sentences in bold type has been continued in this edition, and rivets the attention of the reader on points which the author wishes to impress. The book is calculated to give a clear outline of the general principles which underlie the present principles of diagnosis and treatment in heart affections. By Sir James MacKenzie, M.D., F.R.C.P., LL.D., and John F. F. MacKenzie, M.D., F.R.C.P., LL.D., London: H. K. Lewis, 1923.

day practice of cardiology without tiring the reader with details of the methods which have made present knowledge possible. It can be confidently recommended to the general practitioner, for whom it has been specially prepared.

HALLIBURTON'S "PHYSIOLOGY."

The appearance of the sixteenth edition of Professor Halliburton's *Handbook of Physiology*, brings home forcibly the loss to medical education occasioned by the regretted retirement of the author from the chair of physiology at King's College, London. The severance of this long association seems to mark a milestone in the progress of medical research and education. It may, however, be with some satisfaction that Professor Halliburton is able to feel that he is still, through the pages of his book, in touch with a large number of students, and we hope that he will continue the frequent labour of keeping it up to date.

The book has a fascinating history. In these days of ephemeral publications it is reassuring to be able to look back seventy-five years to the inception of this work. From 1893 to 1896 the book, which bore the title of *Kirk's Physiology*, was edited by a succession of teachers at St. Bartholomew's Hospital Medical School, and this association was only broken when the present author undertook the care of the work twenty-seven years ago. His stewardship has seen a profound remodeling of the whole; sixteen editions have appeared and upwards of 83,000 copies have been printed. In the face of such evidence of sustained popularity little is left to the reviewer but to cry the news of a further edition.

This edition has not been called forth simply at the convenience of the publisher, for the revision of the text has been thorough. The book forms an introduction to human physiology particularly designed to meet the requirements of the medical student. The general sequence of the subject matter has been somewhat altered and the author has succeeded in introducing a great deal of new matter while exerting a wise caution in withdrawing much of the significance of which it is as yet impossible to assay. The student will be grateful for this reticence. A valuable chapter on the bearing of physical chemistry on physiological problems has been introduced and will point the intelligent student to the new lines along which physiology is looking for answers to its old mysteries. The chapters devoted to respiration have been rewritten with the assistance of Mr. J. Barcroft, while Dr. J. H. A. Marshall has been associated with the revision of the subject of reproduction. The authority of this collaboration is token of the sincerity with which the re-editing has been undertaken.

A happy inspiration has led to the inclusion of six portraits of famous physiologists of the past. The personal relations which have meant so much in the earlier progress of science are still very potent, though their influence is not so obvious when so many more are engaged in research, and any gesture which brings the personal touch is a reminder of the individuality of scientific imagination. We commend, anew, this careful labour on behalf of medical and scientific teaching.

Mr. BARNARD GREEN, in his *Manual of Human Anatomy for Dental Students*, has produced the first textbook of anatomy specially designed for the dental student. The need was urgent, and this first authoritative attempt to define the anatomical needs of the dental student will be both welcomed and criticized by teachers, students, and examiners alike. The author's endeavour has been to give a detailed account of the regional anatomy of the head and neck, and "an elementary" description of the remainder of the body, by systems. In the systematic portion only the main facts are presented, but there is sufficient detail and sequence

F.R.C.P., F.R.S., New and sixteen editions. London: John Murray, 1923. (Demy 8vo, pp. xix + 665; 553 figures, 3 coloured plates, 21s. net.)

then the best method was to divide the colon, close the lower end and drop it into the abdominal cavity, and then bring the upper end, still closed, obliquely through the muscles. This would give an artificial anus, admitting of a wonderful degree of comfort. It was well to recall that while new growths were by far the most likely cause of obstruction, they might be very closely simulated by syphilis, which might give rise to a tumour-like mass clinically indistinguishable from malignant disease.

Mr. H. W. CARSON (London) said that he had analysed all the cases of colon obstruction in his practice during a term of twelve years. They amounted to 79 cases, excluding the rectum and intussusceptions. All of these were cancers except 5 cases of diverticulitis and 2 cases of ileo-caecal tuberculosis. He had had no case of volvulus in this series. In many respects they bore out Mr. Burgess's conclusions. Fifty-four per cent. were in the pelvic or iliac colon, 19 per cent. in the caecum or ascending colon, 14 per cent. in the descending colon, 9 per cent. in the transverse colon, and 4 per cent. in the splenic flexure. In 36 cases there was obstruction, or 45.6 per cent., and the order of frequency was—splenic flexure, 66 per cent.; descending colon, 65 per cent.; pelvic and iliac colon, 51 per cent. Only 3 cases were obstructed in the caecum and ascending colon and all of these were affections of the ileo-caecal junction. Obstruction occurred in the right colon—the caecum, ascending colon, hepatic flexure, and proximal half of transverse colon—in 5 of 22 cases, or 22.8 per cent., as compared with 31 of 57 cases, or 54.4 per cent., in the left colon. In a previous series, which partly overlapped this one, reported to the Medical Society of London in December, 1920 (*Medical Society of London Trans.*, vol. xlv, p. 110), he could only attempt a radical cure in 35 per cent. In the last three years he had had better luck and had brought the operability for radical cure up to 52 per cent. for this series. He thought it could be agreed that every case of cancer of the colon should be treated before obstruction occurred, and though that was an ideal and perhaps unattainable, he was not satisfied with the present incidence of obstruction of between 35 per cent. and 50 per cent., especially as it added 20 per cent. at least to the mortality. Sir Berkeley

OWNHAM, at the Medical Society of London in December, '0, said that a discussion on cancer of the colon ought to be opened by a general practitioner who had the chance of seeing these cases early. In order to prevent obstruction supervening they must educate the public to consult their doctor earlier and they must also expect the patient's doctor to suspect cancer of the colon in any middle-aged patient who complained of the cardinal symptoms so excellently described by Mr. Burgess and to treat these patients on medical lines only after the possibility of cancer had been excluded. That raised the question of an exploratory laparotomy if the modern methods of diagnosis failed to exclude cancer as the cause of the symptoms.

There were three types of colonic obstruction due to stricture. First there was partial obstruction, a type which gave rise to the cardinal symptoms of the disease; second was an acute obstruction following a partial obstruction; and third there was the acute obstruction occurring as the first recognized sign. Each of these required different consideration. Partial obstruction was not associated with grave toxæmia, the intestine was not in bad condition, and a planned operation, perhaps in two stages, was possible. Acute obstruction, following on a long-standing partial obstruction, was associated with toxæmia, and also with deterioration of the intestine above the obstruction, particularly marked in the caecum, which was often oedematous, ulcerated, and liable to burst. Acute obstruction occurring as the first recognized sign was but little associated with toxæmia and the intestine above the obstruction was in a more healthy condition. A certain number of these—which might be called unexpected—obstructions were due to oedema of the mucosa at the constriction or even to blocking of the narrowed part by a faecal mass, and practically always occurred low down in the left colon. Immediate operation was not demanded in this last class and the obstruction could often be overcome by giving no food by the mouth, by the administration of morphine, and

by injection of oil and soap enemata. Of course, the closest watch had to be kept on these cases, especially for evidence of toxic absorption, best seen perhaps in the tongue, and also for hyperdistension of the caecum. The real difficulty lay in the cases of acute obstruction supervening on a long-continued partial obstruction. Operation was urgently needed and the question was, what was best to be done? They must exclude all idea of doing a radical cure in these cases, except, perhaps, in favourable cases of ileo-caecal or ascending colon obstruction. He had done several one-stage block resections in such cases with success, and Mr. Burgess in his 9 cases of immediate resection had 2 of the caecum, both recovering. It was probable that even in these cases a two-stage operation was wiser. But in the ordinary case of left-sided colon growth they must be content to relieve the obstruction. Mr. Burgess had raised the question of a blind caecostomy. Mr. Carson did not like it, and for several reasons. First, it was not so easy to differentiate between small and large intestine obstruction. He agreed that they ought to do it, but he could own to having made mistakes. He had even diagnosed as obstruction due to growth of the pelvic colon a case of general peritoneal carcinomatosis secondary to cancer of the stomach, a plaque in Douglas's pouch misleading him on rectal examination. He did not much like Mr. Burgess's 9 to 1 chances. It may be true that a certain condition was present in 90 cases in 100, but it did not follow that it was present in the individual case under notice. Second, there was the danger of overlooking some condition, such as volvulus of the sigmoid, sufficiently rare as it was, which would be fatal if not treated locally. Third, there was the danger of a double obstruction, as occurred in some cases of left colon growth which had involved a coil of small intestine. Fourth, there was the risk of being left with an undesirable caecostomy in an inoperable case which would have been better short-circuited—for example, a splenic or descending colon obstruction. And fifth, there was the danger of having to deal with a caecum in such a bad condition that manipulation might cause faecal extravasation. This particularly referred to long-standing obstruction with acute symptoms supervening. He liked to see what he had to deal with, and particularly to be sure if the case was a possible one for radical cure. If there was a chance of a subsequent resection he was all in favour of a temporary caecostomy, which was the best thing to do. It relieved the obstruction and was of real value after the radical operation, as it prevented distension above the suture line. He did not like the Mikulicz operation, as he thought it was unsound from the block resection point of view. If there was no chance of a subsequent radical cure he thought a caecostomy should be avoided if possible. In these cases, if the obstruction was low down an inguinal or even a transverse colostomy was better. If the obstruction was higher up, some form of short-circuit was generally possible, not a unilateral exclusion, but a simple lateral anastomosis. Mr. Burgess's success with lateral anastomosis was very gratifying—3 deaths only in 11 cases and one of those the very difficult descending colon-sigmoid anastomosis. There was one point about these lateral anastomoses which wanted emphasizing. Every effort should be made to avoid the long blind end. For instance, a caeco-sigmoidostomy was not an ideal operation in inoperable transverse colon growths, nor was an ileo-sigmoidostomy in a splenic flexure growth. Of course, these short-circuits were meant to meet the emergency and in such a case, for instance, an ileo-transverse colostomy for hepatic flexure growth must be supplemented by a drainage of the section between the growth and the ileo-caecal valve; but this might be done after the acute symptoms had subsided. To sum up, Mr. Carson said that the treatment of colonic obstruction was fairly well standardized, but greater efforts should be made by propaganda and the training of students to diagnose colon growths early and thus anticipate the onset of obstruction.

Mr. J. P. LOCKHART-MUMMERY (London) observed that the figures Mr. Burgess produced showed that the percentage of mortality from acute obstruction of the colon, excluding intussusception, was 32.16 per cent. He thought

## THE STATE OF THE PUBLIC HEALTH.

The annual report of the Chief Medical Officer of the central Government department concerned with the public health has always been studied with interest by the medical profession from the time when Sir John Simon, the first incumbent of such an office, was writing his pioneer reports for the Privy Council, through the long series of annual reports presented by succeeding principal medical officers of the Local Government Board, to the most recent presented by Sir George Newman to the Minister of Health; it is his fourth as Chief Medical Officer to the growth of the science and art of hygiene may clearly be followed. The general scope of the new report can be gathered from the analysis begun in our last issue and concluded in this (p. 578).

Looking back on the series we may clearly see a shifting of the central interest. The earlier reports were concerned largely with the principles of administration—the need for central and local authorities to supervise and control municipal sanitation, their contribution, their finances, and the definition of their duties and powers. Then came a long period during which local authorities were concerned chiefly with larger local authorities were concerned chiefly with disease in the mass, with water-borne disease in particular, and great cities such as Glasgow, Manchester, Liverpool, and Birmingham undertook huge and costly engineering works, not unworthy of the Romans, to provide themselves with an abundant supply of pure water. It was at this stage that the work of the British Medical Association, of the Army Medical School, of voluntary organizations, and of many public-spirited members of the medical profession, was of such incalculable value in educating our rulers and administrators, so preparing the way for the creation of a Ministry of Health. The very name marked an epoch, indicating that the preservation of health and the prevention of disease was to be the primary duty of an important ministry of State, and no longer of a subsidiary section of a department mainly concerned with other matters which, to the Minister and the permanent officials, seemed to be of greater consequence. During all this middle period Great Britain, and England in particular, was not only learning great lessons, but teaching them to the world. The application of intuition seems particularly congenial to the English mind, which is at once imaginative and practical, but great Britain were arresting, and the interest of foreign nations thus aroused was confirmed by the foundation and growth of the new science of bacteriology, which was able to explain some of the British generalizations and to give greater precision to matters of detail. It was, of course, very soon seen that certain problems were the same for all European countries

and for parts of North America, and very similar in respect of the introduction of exotic epidemic diseases. For the discussion of this last matter the medical department of the Local Government Board had already begun the collection of material, and for many years the late Dr. Nissen Haddiffe in annual articles kept track of cholera, plague, and many other diseases, recording the rise and fall of endemic prevalence and the origin, spread, and decline of epidemics. Presently the International d'Hygiène Publique was established in Paris, and the Port Sanitary Service came into existence here. This international side was another reason why we should provide ourselves with a Ministry of Health. The Intelligence Division is now an important part of the Ministry, collecting information—administrative, legislative, or statistical—which helps the due discharge by this country of its obligations in international as well as national affairs. We seem now to be entering on a new stage, and in the report of the Chief Medical Officer for 1922 much emphasis is laid on the duty of the individual citizen. It is an old and well established principle of law that a man must not so conduct his home or his business as to injure his neighbour, and sanitary laws consist of little more than application of this general principle to the prevention of machinery for mass sanitation we passed to the creation of machinery for mass sanitation we passed to the prevention of disease in the mass; now we have begun to require the individual to safeguard his own health and the health of his family. We pass from individual rights to individual duties.

Sir George Newman has not hesitated to use the argument *ad hominem*. In public and private medicine, he writes, the aspect of the individual is needed "if the individual is to reap his full advantage, and at the same time to act loyally as a member of the community; in fact, he is under obligation to cultivate his own health and capacity, and so to conduct himself as not to conduce to the hurt or risk of his neighbours." Finally, as was to be expected, we are presented with the argument *ad communem*—if it pays the individual to look after his own health and the health of his children and of the mother of his children, it will pay the State to help him to do so. But times are hard, and the difficulty about schemes for promoting individual hygiene is that the expenditure on them is new and obvious to the individual ratepayer. Not the most short-sighted of municipal economists will propose to scrap the waterworks at Loch Katrine, Thirlmere, Rhayader, or Ynnw, and leave Glasgow, Manchester, Liverpool, and Birmingham without water, but it is quite easy to nibble at estimates for clinics. The Ministry of Health, we are told by its Chief Medical Officer, is being very careful about money, and has taken steps "to curtail local authorities on the financial aspects of their work"—a phrase to be interpreted as we will; but Sir George Newman is no defender of economy at any price, and we may take leave of his report by quoting its concluding sentences. "If the public expenditure on the health of the nation is every year saving the lives of many thousands, as this Report shows, and if it is prolonging the life of others, or increasing or continuing their capacity for productive work, as is absolutely certain, I submit that it is an economical and profitable expenditure in the correct sense of the terms. For the truest national economy at this moment is to spend productively and increase the earning capacity of the individual."

upon with an absence of danger that had to be experienced to be realized. His own belief was that inhalation anaesthesia should not be used in old people or in persons suffering from acute abdominal conditions.

Professor CHARLES A. PANSETT (London) said that the knowledge that their treatment of any disease was very remotely removed from finality was a constant impetus to review beliefs as to the propriety, usefulness, and efficacy of any particular methods they were using. In the treatment of acute obstruction of the colon, the procedure to which he had given the name of "blind" caecostomy had proved a very satisfactory one in numerous cases; there was very much to be said in its favour, its value was vouched for by some of the greatest amongst abdominal surgeons, but was it not possible that its advantages were rated too highly, and had not its very real drawbacks been rather thrust into the background? If the abdominal organs were immersed in transparent walls, it would be much easier to choose their plan of campaign; but when confronted with an extremely ill, tensely distended patient, who had reached a stage of his disease when he was too listless and apathetic for them to be able to place implicit reliance upon his replies to inquiries, Professor Pannett confessed that sometimes his diagnosis of large bowel obstruction was rather a guess than an opinion based upon knowledge. That was the primary difficulty. Quite recently, however,

marvellous powers of recovery these patients have. After many days' obstruction, with distension so extreme that the loss of the support of the abdominal wall brought about by its incision allowed the caecum to split from internal pressure, he had seen patients recover and pass successfully through an excision operation. In these very late cases, it must be a procedure of great skill to pull an area of caecal wall through a small gridiron incision without rupture, for the viscus was as tense as a rubber balloon. Through a paramedian incision the distension could be immediately diminished by the use of a hollow needle and under conditions of free access, with little danger of infection. It was not necessary to allow coils of intestine to protrude on to the surface of the abdomen—the proper place for the abdominal viscera was within the peritoneal cavity. Neither was the trauma of the gentle insinuation of the exploring hand of significance in comparison with the worst of all shock-producing stimuli, the overstretching of the bowel wall which was already present. The subsequent suture of the abdominal wall was not so difficult as they might suppose, for at that stage evacuation through the caecostomy would have considerably reduced the distension. It was facilitated by using the three-bladed forceps which he devised some years ago. He had never seen adhesions from around the growth as a result of manipulation, unless it lay immediately under the wound, and then they had not been serious.

FIG. 1.

FIG. 2.

FIG. 3.

FIG. 4.

x-ray investigations in patients suffering from acute intestinal obstruction had shown that it was sometimes possible to determine the site of the obstruction beforehand, without giving barium, if it were in the large intestine. For the bowel distended with gas above the obstruction was recognizable by its characteristic sacculatation, whilst the contracted bowel below gave no obvious appearance on the plate. It was also asserted that, after washing out the stomach, a little barium cream, given to a patient suffering from acute obstruction of the small intestine, would rapidly be propelled to the site of the block, where it would be held up sufficiently long to be demonstrated on the x-ray screen or plate. That method of investigation was worth trying. If it were established on a firm basis it would make all the difference to the attitude with which they approached these doubtful cases, for simple caecostomy could only be performed with equanimity when the diagnosis was a certainty. At St. Mary's Hospital, of the 47 cases of carcinoma of the colon (excluding the rectum) treated during the previous three years, not one death occurred as the immediate result of caecostomy combined with abdominal exploration, and every patient with acute obstruction was submitted to a primary exploration. So that this procedure did not appear to be a very fatal one. There was, however, a death after primary exploration combined with colostomy, which operation was very much the same. This occurred in a feeble woman of 67; there were very extensive secondary growths in the abdomen, the primary one being in the splenic flexure. Transverse colostomy was performed; the patient was not acutely obstructed at the time, but suffered from persistent bloody diarrhoea. When they looked at the disease they could not but be struck by the

To consider another aspect, they found that of the cases of carcinoma of the colon coming to St. Mary's, only in a little more than one-third of the total number did conditions allow of excision of the growth. Of the remaining two-thirds, more than one-half had to pass the remainder of their lives with a permanent faecal fistula, a short-circuiting operation not being possible. Now these unfortunates, with but a small residue of life, had to suffer the distress of another abdominal operation, if a blind caecostomy were done. For the greatest comfort the fistula should be made as close to the growth as possible, and there also it would drain the best. A primary colostomy in irremovable growths was more effective than caecostomy, and a second operation was eliminated. When a "blind" caecostomy had been performed, they usually tried to ascertain the exact site of obstruction by means of sigmoidoscopy or the opaque enema. It was often not possible to see the growth through the sigmoidoscope, even when it was in the sigmoid, for adhesions of the growth and adjacent bowel might prevent distension and the straightening out necessary to pass the instrument. The opaque enema also did not always give them unequivocal information. In 1911 he operated upon a man with acute obstruction; the caecum and transverse colon were distended, and he made what he thought now was the erroneous observation that the sigmoid was not. Without being able to feel it in that area, he made the deduction that there was a growth at the splenic flexure. The opaque enema was to be seen in Figure 1. It supported the previous diagnosis. At the subsequent operation there was no growth in this region, but there was an irremovable carcinoma of the sigmoid. This spasm of the splenic flexure he had seen in

made them live and more, is in the position of a man who has cut the leaves of a book and thrown it away unread. Our author would have medical students and medical men, as each manifestation of structure or of disease meets their attention, ask themselves a perpetual "Why?" and never rest until they find a reasonable answer or explanation. He would have his students, as they examine sections under the microscope, to remember that what they see are artificial snapshots of the living units which carry on the work of the body. Above all, he would have medical students, in these days of crowded curricula, cultivate a sense of perspective, and discriminate between the important and the unimportant. The tradition which has clung to our British chairs of anatomy—that their occupants should be men of wide interests—finds a true representative in Professor Whittall. In this booklet he places at his pupils' disposal a rich experience gleaned from a close study of how men should order their careers if they would take the best out of life.

WATER POISONING.

The toxicity of pure, fresh, or distilled water for fish, for

investigated since the time of Paul Bert, who in 1865 ascribed the toxic effect of fresh water on mullet to the difference in osmotic pressure between fresh and sea water causing the tissues to absorb water in excess. A short time ago (June 29th, p. 996) we gave an account of the results of an inquiry by Dr. J. S. Haldane and Mr. K. N. Moss on the effects of high temperature and muscular exertion upon colliers and stokers, from which it appeared that the ingestion of unusual quantities of water might lead to attacks of "cramp," spoken of as "miner's cramp" or "stokers' cramp," believed to be due to a form of "water poisoning."

For example, observed to be due to a form of water poisoning or the muscles brought about by the combination of great loss of chloride by sweating, excessive drinking of water, and temporary paralysis of the renal excretion. Last year Larson, Weir, and Rowntree described a peculiar form of intoxication in patients with diabetes insipidus, who after hypodermic injection of pituitary extract continued to drink the same quantities of water that they had previously been accustomed to take. Patients manifested severe toxic symptoms—headache, patients manifested severe toxic symptoms—headache

After some experiments on animals the authors concluded that this intoxication could not be induced by water alone but by pituitrin alone, but only by a combination of the two. Rowntree has now published the results of a further research on the production of water intoxication in dogs, cats, rabbits, and guinea-pigs without injection of pituitary extract; it therefore appears that pituitary extract was not the occurrence of water intoxication by hypotonic solutions.

[illegible]

was found to prevent water infiltration. Various injections of hypertonic saline solution over a longer time, intravenous injections or peritoneal dialysis were also tried without success.

WE have received from Dr. N. H. Choksy, C.I.E., Bombay, a reprint of seven articles which he contributed to the *Times of India* during May and June of this year on plague in India and other cognate subjects. Choksy, whose name is well known in connection with study of infectious diseases in India as medical superintendent of the Arthur Road Plague and Infectious Hospital and the Maratha Plague Hospital, Bombay, explains in a short preface that his object in writing articles was to focus public attention on the ravages of plague in India during the last twenty-five years, to consider whether there is any probability of eradication

the disease at an early date, and to show that nothing had been done by the Government of India to discover a remedy for it. He has also been anxious to obtain concerted action in order to combat the excessive mortality in India, not only from plague, but also from a number of other preterrible diseases. The Indian Cross Society, which has attempted to do so, can, however, justify remarks, the fringe of the problem as they do less than five lakhs of rupees annually by the most strenuous efforts. Its resources, amounting as they do to less than five lakhs of rupees annually, could not cope with the needs of a vast continent like India. Dr. Choksy therefore appeals to the Government to take control, and suggests that a special sanitary, preventive, and curative service under a Ministry of Health should be established in each province, and that there should be a central body to co-ordinate the work of these

provisional legislatures and the Legislative Assembly should be established in each province, and that through articles cover ground already well traversed and expounded in India and awaken the masses to the need for active co-operation in sanitary measures. As he truly says, the masses in India are not yet ready to assimilate the lessons of an intensive campaign of sanitation. What they require is actual and concrete demonstration of the benefits promised and implied, and appeals for such actual demonstration to accompany, rather than precede, any intensive campaign of instruction. Without question he is applying his knowledge better still to precede, any intensive campaign of instruction. Without question he is applying his knowledge better still to precede, any intensive campaign of instruction.

the difficulties of the sanitary problems in the present direction. He has no illusions as to the magnitude of the task which he has undertaken. He has no illusions as to the magnitude of the task which he has undertaken. He has no illusions as to the magnitude of the task which he has undertaken.

...and medical assistance for the health of the people, with a director and assistants, and a provincial health service, with a director and assistants, in one or two localities where an outbreak of plague is threatened. The communities of 25,000 to 50,000 inhabitants, such as the provinces, towns, schools, and universities, are to be organized as provincial communities. This requires an adequate service, that is to say, which is broadcast over

question having proved to be, as he expected it would, the treatment of the Group II cases. He admitted that the "opportunistic" view expressed by Professor Pannett, Mr. Childe, and other speakers—that exploratory laparotomy should be the first step in all cases where one considered the patient's general condition sufficiently good to withstand it, and that blind caecostomy should be reserved for the others—seemed at first sight logical and tempting. It was probably the practice of the majority of surgeons at the present time. But the difficulty was to know how much the patient would stand, and if the present high mortality of these cases was to be reduced some change of the present practice must occur. Although, in general terms, he shared the dislike expressed by some of the speakers to any routine procedure, yet in this particular instance he felt convinced that the routine adoption of blind caecostomy would very materially lower the mortality, although earlier diagnosis must remain the most important factor in that connexion. He did not agree with Professor Pannett that an exploratory laparotomy did not add to the risk of caecostomy; it was not easy to show this by figures, but it appeared to him to be axiomatic. He was interested in what Mr. Barling and Professor Pannett had said as to the diagnosis of the site of obstruction by the use of the x rays without bismuth meal or enema. Unfortunately most of the patients in the acute type of obstruction he had been considering were too ill to be sent for even a short radiographic examination. He had not found cleansing of the colon proximal to the obstruction to be so impossible after caecostomy as Mr. Barling suggested. Any faecal matter remaining in it would in any case, as the result of the caecostomy drainage, have been deprived of its acutely toxic properties, and would not prevent restoration of the bowel wall to a healthy state. By repeated flushings of the colon, both through the caecostomy and per anum, he considered that the bowel could be effectively cleansed in from ten to fourteen days. In many cases, after the relief to obstruction by caecostomy, the passage through the obstructing growth became restored, and fluid would pass from the anus to the caecostomy opening. Mr. Mothersole had suggested that it might be advisable, where there was a long length of colon between the caecum and the growth, to perform a second drainage operation—in other words, a colostomy just above the growth—before undertaking the radical extirpation. He did not think this would be necessary if sufficient time and attention were given to careful flushing of the colon.

### ARE THE RESULTS OF THE OPERATIVE TREATMENT OF CANCER BETTER THAN TWENTY YEARS AGO?

BY

HERBERT J. PATERSON, C.B.E., M.C.CANTAB.,  
F.R.C.S.,

Senior Surgeon, London Temperance Hospital.

It is peculiarly appropriate that this question should be discussed at the headquarters of the President of the Association, who has done so much to promote the early recognition and the early treatment of cancer. I imagine that there are few of us who do not feel depressed at the poverty of our success when we reflect how small is the number of cases in which complete freedom from recurrence follows operation for cancer. Yet there is no doubt that during the past quarter of a century surgical technique has been greatly improved, many of the risks of operation have been very materially lessened, and this in spite of the fact that the operations practised for malignant disease have become more extensive and radical. But from the point of view of remote results have we similar cause for satisfaction? I look in vain for any convincing evidence that the proportion of ultimate successes is greater than was the case twenty years ago.

The Registrar-General's returns show that in the year 1921, of each million persons living, 1,215 died of cancer, as compared with 828 per million persons in the year 1900, an increase of nearly 30 per cent. Even granting that cancer is on the increase, and that death certification is more

accurate, it is not easy to understand this proportional increase if modern operations have effected the cures which are claimed. A comparison of operative statistics seems to point to the same conclusion. Most of us have had isolated cases of freedom from recurrence for ten or even twenty years, but on the whole the proportion of those free from recurrence after five years appears to be about the same as it was twenty-five years ago. When I was house-surgeon I traced the results of the operations for mammary cancer performed by my chief, the late Mr. Alfred Willett. I found that 42 per cent. of the patients were free from recurrence after three years, and 33 per cent. after five years. In 1902 Mr. T. Bryant published a series of cases showing 50 per cent. free from recurrence after five years, and 32 per cent. alive and well after ten years. It is not without significance that both these surgeons practised what to-day would be considered a very inadequate operation. The axilla was not cleared out as a routine measure, but only when there was evidence that the glands were diseased. It is interesting to compare these figures with those of Halsted, as the result of the more radical operation known by his name. In spite of a more extensive operation his results appear no better than those I have quoted. He reported 46 per cent. of the patients dead within three years, and 41 per cent. alive and free from recurrence after three years. As regards carcinoma of the rectum, Mr. Harrison Cripps was able to report that 42 per cent. of his cases were alive three years after operation, and almost all of them were perineal excisions. Not many of us can show better, if as good, results as these. Unless we can prove our efforts to be more successful we are living in a fool's paradise.

Is there any fault in our technique or method of attack to account for this apparent lack of progress? I would suggest two questions.

First, are we allowing the teaching of pathology to override clinical experience? No one has greater regard for pathological work than myself, but I am inclined to think that some of the conclusions arrived at in recent years have tended to hinder rather than to further progress. Pathologists tell us that cancer cells are scattered far and wide beyond the apparent limits of a growth, and consequently they urge the necessity of wide and extensive excision. Indeed, if we were to accept their conclusions as gospel it would in most cases seem useless to attempt resection of bowel for carcinoma. We know, however, from clinical experience that operations in which the margin of the growth is very close to the line of resection are sometimes followed by a long interval of immunity. The microscopic observations may be accurate, but the inferences drawn therefrom are not necessarily infallible. If it be true that cancer cells extend far beyond the site of the growth, the conclusion is irresistible that the tissues can and often do destroy the isolated cells which are left behind beyond the line of excision. To this extent I submit pathology has led us astray. Our efforts have been directed towards more extensive operations, whereas earlier diagnosis and earlier operation should be our aim.

The second question I would put is this: May it not be the case that in modern surgery the lymphatic glands are attacked too ruthlessly?

Do we fully appreciate the part played by the lymphatic glands in Nature's defence against the spread of carcinoma? If, by operation, all the neighbouring glands are removed, may we not be depriving the patient of his first and main line of defence? There can be no doubt that cancer cells spreading from the primary growth are arrested, at any rate temporarily, in the neighbouring glands. Possibly the glands may be able even to destroy a limited number of cells, when the primary focus has been removed. Most of us have met with cases in which operation for malignant growth of the bowel has been necessarily incomplete, in that glands obviously infiltrated with carcinoma have been left behind, in spite of which the patient has lived ten, twelve, or even more years. It is a fair inference that such patients have remained well not in spite of, but because of the incomplete removal of glands. It is difficult to explain such happenings except by the hypothesis that the cancer cells left behind have been destroyed by the healthy tissue in which they were unwelcome guests.

these impressions in its structure, to be violently shaken by a blow on the skull; the whole delicate structure will be thrown out of gear, and the immediate result is the total abolition of consciousness. Soon, however, if the blow be not too severe, the shaken elements go back to their places and consciousness returns. But in the general shaking and arrangements may be so badly shaken that they are altogether obliterated, and those most likely to be affected are those most recently formed or in the process of formation. This is a plausible explanation of both pre-traumatic and post-traumatic oblivion.

#### RESEARCH IN MENTAL HOSPITALS.

The ninth annual report of the Board of Control, which deals with the year 1922, is for the most part in the usual form, but it contains an appendix setting out more fully than is customary the research work that is being carried out in a number of mental hospitals with the encouragement of the Board, and also at the pathological laboratory of the Maudsley Hospital. Among the researches mentioned is that on the physiogenic origin of dementia praecox in the last named laboratory, upon which was founded Sir Frederick Mott's British Medical Association Lecture on the reproductive organs in relation to mental disorders published in our issue of March 25th, 1922, and those described in the article by Sir Frederick Mott and Dr. Isabel Hutton on the adenoma with special reference to dementia praecox, published in our issue of July 21st, 1923 (p. 53). The appendix also contains a rather long report by Mrs. Shaw Bolton and McGrath on asylum dysentery and allied infections. Another report, by the medical officers of the Lancashire County Mental Hospital, gives a good idea dealing generally with the researches now in progress in the causes of mental disorder and defect. A reference is made to the establishment at Birmingham of a joint board of research, consisting of representatives of the University and of the City Mental Hospital Committee, and of the appointment of Sir Frederick Mott to be director of research and lecturer on psychotherapy in the University. The Board declares its readiness to help the establishment, in connexion with each university in England and Wales, of similar research centres having affiliated with them every neighbouring institution in which mental cases are received. These centres would serve as a link between other branches of medicine and the psychological branch, and would conduct researches which cannot be undertaken in a comparatively small clinical laboratory. At the same time the Board expresses the view that no mental hospital should be without a laboratory, and that arrangements should be made whereby work will be systematically carried on in each laboratory either by a member of the resident medical staff or by a part-time visiting medical officer. It is hoped that the interchange of information, and facilities will conduce to the improvement of research centres and duplication of the results obtained so as to avoid needless duplication of effort. We hope to return to this report and its appendices on an early occasion.

#### DRUNKENNESS.

The annual blue book of licensing statistics for England and Wales for 1922 has been issued (Cmd. 1925, price 6s.). Convictions for drunkenness are not, of course, a completely satisfactory measure of the prevalence of the vice, as probably only very marked cases and their way into the police courts; yet so far as they go those for 1922 are encouraging. The convictions in England and Wales for 1922 numbered 76,347, a decrease of 1,442, or 1.85 per cent. The reduction was not uniform throughout the

#### THE ROTUNDA HOSPITAL, DUBLIN.

more numerous than in bad times.

The Rotunda Hospital statistics for the year November, 1921—October, 1922, compiled by Drs. Gibbon Fitzgibbon, J. S. Quin, and G. W. Theobald, show a decrease of 260 admissions, and 51 confinements in the hospital, but the external confinements increased by 256. The mortality for indoor cases was 8 deaths in 1,715 cases. In the 2,622 cases attended outside there were 10 deaths, 5 of which were due to post-partum haemorrhage; in all of these the child was born before the arrival of the attending student, and in 4 the patient was moribund when first seen. Five cases of ante-partum bleeding occurring in the outdoor district were "packed" before being sent into hospital, without any untoward results, showing that packing could be performed aseptically even under bad conditions. Regarding the statistics for abnormalities connected with pregnancy and labour, the cases of placenta praevia and eclampsia during the year were very few, only 19 of the former and 14 of the latter, as no maternal deaths occurred in any case suffering from either complication the results are extremely satisfactory. With regard to vaginal plugging for placenta praevia—in accordance with the Rotunda doctrine—Dr. Fitzgibbon and his colleagues state that much doubt has been cast on the efficiency of this method and that many cases of sepsis have been quoted; they assert, however, that this is due in the first place to inefficient plugging (cotton wool pledgets should always be used, and not gauze or other material), and in the second place to packing or other wool pledgets should always be used, and not gauze or other material), and in the second place to packing or other wool pledgets should always be used, and not gauze or other material).

laryngo-fissure was, in his early cases, 25 per cent. Of Bullin's 9 cases between 1886 and 1890, 3 died of the operation, 3 died of recurrence, and though the other 3 survived, sufficient time had not elapsed to claim a success.

Thirty-three years later what was now the position? Laryngo-fissure was a well established operation and secured lasting cures—some 80 per cent.—which surpassed the results obtainable for cancer in any other internal region of the body. In 60 cases Sir StClair Thomson had only had 3 deaths—one from rupture of the oesophagus from post-anaesthetic vomiting, one from an idiosyncrasy for heroin, and one from morphine. Not one of these cases could be properly called an "operative death." Of his 57 cases, 25 were alive and free from recurrence after three to fourteen years, 8 after one to three years, 4 under one year, so that a total of 37 were alive to-day. Thirteen patients died of other disease without recurrence; of these, 8 had passed the three-year period. These, added to the above 25, would make 33 who, out of 57, had passed the three-year limit. Another chart showed the advanced age of many of the patients. Six were over 70. One operated on at 75 was to-day alive and well at the age of 81. A patient of 80 was operated on successfully. Only 8 patients out of 57 died from local recurrence, and 2 from recurrence in the glands.

Still better results would be obtained as the disease—always indicated by persistent hoarseness—was diagnosed earlier. If cancer was limited to a vocal cord and was operated on with every care, they had in laryngo-fissure an operation which could now be made safe in execution and certain in its results. The operative death rate should be nil, a serviceable voice could be promised, and there was every prospect of permanent freedom from recurrence. Therefore, in reply to Mr. Paterson's question as to whether there was any recent improvement in the results of operation for cancer, Sir StClair Thomson asserted that, so far as intrinsic cancer of the larynx was concerned, the reply was most unhesitatingly in the affirmative.

Dr. MAJOR GREENWOOD (London) said that he ventured to intervene in the discussion because one aspect of the general problem before the Section was directly relevant to the work of a Departmental Committee of which he was a member.

It was the duty of the medical statistician to scrutinize closely the rates of mortality from malignant disease chiefly in the hope that, having discovered differences which transcended the possibility of explanation on mere book-keeping lines—that was, as mere errors of record or definition—he might be able to suggest problems for the consideration of both laboratory and field workers. The statistician was not anxious to waste the time of his colleagues in the exploration of mare's nests, and therefore paid especial attention to the data gathered in countries where the level of professional education was high and the statistical system well developed. When both these conditions were fulfilled, it was found that very striking differences of fatal incidence of malignant disease existed. An important example was afforded by the confrontation of the rates of mortality from cancer in England and Wales, in Italy, and in Holland. Details were contained in his note, communicated to the Office International d'Hygiène Publique, "*Différences internationales dans les taux de la mortalité par cancer*" (Bull. de l'Off. intern. d'hyg. pub., xiv, 1922, p. 1507), and he wished merely to recall salient features, which were as follows. Although the death rate from cancer as a whole was no lower in Holland than in England and Wales, indeed slightly higher, the death rate from cancer of the breast and female generative organs, making due allowance for differences of age distribution, was almost twice as great in England and Wales as in Holland. For instance, in 1919, taking the Dutch rate as 100 in each case, the figures for England and Wales were: age group 40 to 50—breast 169, generative organs 170; 50 to 65—breast 159, generative organs 184; 65 to 80—breast 203, generative organs 181; over 80—breast 235, generative organs 156. This was a very remarkable contrast and to discover its explanation was obviously a matter well worth consideration. Plainly one ought to deal with

possible explanations in order of their *a priori* probability. He thought that the explanation which first suggested itself and would surely be considered worthy of examination by members of the Section was that, for some reason unknown to them, cases of cancer of the breast or uterus came up for examination and surgical treatment at an earlier stage, on the average, in Holland than in this country. Now there was no insuperable difficulty in the way of a comparative study of the surgical experiences of English and Dutch hospitals; in fact, steps had already been taken to effect such a comparison. But the statistician was at once faced by the difficulty of standardizing the experiences of different surgeons. An examination of the literature—his colleague Dr. Janet Lane-Claydon was then making a detailed study of the literature—showed that the data published by various surgeons were far from being of equal value owing to the non-uniformity of the system of recording. Confining himself to the particular case of cancer of the breast and speaking, of course, subject to the correction of experts, it would seem that the method of recording adopted by Professor Halsted, with a slight modification, approximated closest to the requirements of a genuine comparison. One required to have stated with respect to each patient, in addition to her age and marital history—both important items—the finding of the surgeon on examination, which might, he thought, be classified thus: (1) a tumour, neither adherent to skin nor deep structures and no palpable change in the axillary region; (2) as (1), but with palpable glands in the axilla; (3) a tumour adherent either to skin or chest wall and with palpable axillary glands; (4) a tumour adherent to both skin and chest wall with palpable axillary glands; (5) either of the preceding states together with palpable glands in the supraclavicular area. That grouping did, he suggested, on the average, correspond to an increasing gravity of prognosis. If then it appeared that the proportions of patients at admission to general hospitals of the countries compared and classified in those groups were significantly different, they would have at least *prima facie* evidence that their surmise was correct, that the frequency of resort to early surgical treatment sensibly affected the death rate. Of course they would hope to learn a good deal more than that from properly standardized statistics; they would hope to learn what was the average numerical measure of the advantage derived from operation, but he desired to put the case for standardization at its lowest. Many surgeons believed that at present there was much preventable loss of life owing to the failure of the public to avail themselves of early treatment; nobody there was likely to dissent from that opinion. But when it was a question of inducing the public by some form of propaganda to avail themselves of what could be done, there was much difference of opinion as to what should be said; some thought that the danger of promising more than could be performed was a real danger. He had devoted too many years to the study of medical statistics to be under any illusions as to the infallibility of numerical statements; a piece of statistical reasoning which was entirely fool-proof had not yet been submitted to the world. But he was optimistic enough to believe that a statistical survey of the after-history of operated cases made by surgeons and statisticians working in loyal collaboration would not only yield valuable matter for the education of the public but would be a sensible, if modest, contribution to the study of aetiology and prognosis. A first desideratum was an agreed clinical classification, one which secured at least as general agreement amongst surgical experts as did, for instance, the Turban-Gerhardt classification of the clinical stadia of pulmonary tuberculosis. He thought it would be generally agreed that recent studies of prognosis in phthisis were more exact than those of a generation ago and that that improvement was largely a consequence of standardization. Perhaps in some forms of malignant disease—for instance, of the breast and tongue—the difficulties of standardization were not greater than those met with in classifying phthisis. In others—for instance, malignant disease of the stomach—the difficulties were surely much greater; but in all cases they could improve upon the present condition.

MEDICAL EDUCATION:

SIR WILLIAM P. HERINGHAM, K.C.M.G., M.D.,  
CONSULTING PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL;  
MEMBER OF THE UNIVERSITY GRANTS COMMITTEE.

The institution of the medical and surgical units in London was an attempt, originally begun by the Board of Education and continued by the University Grants Committee, to give

a more scientific character to medical education. Users and others had criticized the teaching of the final subjects and no one had criticized the later dissemination of this information. The group had criticized that it was not practical, and had not separated the later dissemination of this information.

some system was introduced by which men were well reversed in the latest work of the mathematical and natural sciences.

under various additional conditions as would enable them to employ in their important teaching positions, and to place in positions of responsibility and to give them the clinical problems of human disease the same method.

as were in use among the physiologists and pathologists. They admitted that the clinical teachers were in touch with the heads of the laboratories and regularly sought their

assessments, but they argue, particularly, that the best teaching is not done in clinical work and had been undervalued for years.

part recent discovery were, they said, incapable of giving themselves the laboratory methods now required for the discovery of new medicines.

importance of such work. English teachers were especially important in the care of the deaf and dumb, and rendered great service in distinguishing and describing diseases and the conditions of the body.

observation. Not only was observation itself largely trans-ferred to the microscope, but also the laboratories had

imported the methods of experimentation and verification into many regions where observation had hitherto been employed alone, and with this change had arisen a different way of

looking at clinical problems and a greater hope for their solution. In England no provisions existed such as were found in other countries whereby men could if they wished donate their organs for transplantation.

teaching of students than for earning their living by seeing patients, and until there was some sufficient payment for such non-French educational services.

English medicine would not rank with that of other countries. A professorial system was advocated much like that in force throughout Germany, whereby a clinical

division of the hospital, with properly equipped laboratories attached to it, should be placed under the control of a chief chosen for scientific distinction, around whom should

be grouped a staff of younger men to be engaged in research under his guidance, and to assist him in the education of students.

these laws, which were promulgated more than ten years ago, were approved by medical teachers and by the Board of Education, and steps were taken to bring them to a practical issue. But the war intervened and nothing

could be done at the time. As soon, however, as peace returned the Board of Education again took up the question, and began in a few of the London schools the trial of what is known as the unit of English.

embodied. In 1919 the University Grants Committee took over the university work of the Board of Education, and continued its policy. Medical and surgical units have been

| Group 2:         |                  |                                                                  |
| Firm A ...       | 67               | —                                                                |
| Firm B ...       | 66               | —                                                                |
| Firm C ...       | 66               | —                                                                |
| Group 3:         |                  |                                                                  |
| Firm F ...       | 56, 50           | —                                                                |
| Firm E ...       | 38               | —                                                                |
| Firm H ...       | —                | 31                                                               |

With the exception of the preparations from Firm A, who have kindly supplied me with numerous samples, these preparations were obtained at random to gauge the average value of the products on the market. The results obtained have been divided into three groups on the basis that all tablet preparations should have an activity index of over 50, and powders over 70. This is based on the following:

|                                 | Activity. |
|---------------------------------|-----------|
| Whole glands ...                | 106       |
| Desiccated powder from same ... | 93        |
| Tablet from same ...            | 76        |

With the preparations in Group 1 good results were obtained clinically in suitable cases, whereas with one of the Group 3 preparations no therapeutic effects were obtained in similar cases. In another instance samples of dried tissue, submitted as parathyroid glands were tested by the method described. Of these samples, specimens A and B were histologically unlike parathyroid gland; specimen C was known to be parathyroid gland by dissection and histological appearance. The activity figure was as follows:

|                | Activity. |
|----------------|-----------|
| Specimen A ... | 23, 29    |
| Specimen B ... | 14        |
| Specimen C ... | 71        |

4. Differentiation of parathyroid preparations from other gland preparations. It must be remembered that substances may be present in tissues and tissue extracts which prevent the precipitation of guanidine by picric acid in varying degree. Of these arginine is known to be one and nucleic acid is very probably another. There is also the possibility that other gland substances may have some degree of activity upon guanidine salts.

The following gland substances have been tested under the standard conditions; in all cases desiccated powders were used.

| Substance.              | Activity.                    |
|-------------------------|------------------------------|
| Parathyroid ...         | 100, 93, 100, 85, 67, 66, 66 |
| Thymus ...              | 110, 114, 106, 116           |
| Lymphatic glands ...    | 88                           |
| Thyroid ...             | 26, 11, 16                   |
| Suprarenal, total ...   | 37, 32                       |
| Pituitary, anterior ... | 33, 30                       |
| " posterior ...         | 39, 42                       |
| Orchitic ...            | 45                           |
| Ovarian, total ...      | 18                           |
| " residuo ...           | 28                           |
| Corpus luteum ...       | 43                           |

The difficulty therefore lies in the means of differentiating between parathyroid, thymus, and lymph glands. This can be done by estimating the activity every day over the period of the test, instead of only at the end. If the figures so obtained are plotted in the form of a graph, quite dissimilar pictures are obtained. (See figure.) The appearance of the thymus and lymphatic gland curves suggests that some substance is dissolved which prevents guanidine precipitation and which gradually disappears under the conditions of the experiment. The parathyroid curve, on the other hand, suggests the possibility of some ferment-like action upon the guanidine.

These are some practical points in connexion with the test, and it is hoped that this method may be found of use in controlling the therapeutic value of

## THE TREATMENT OF HYPOTHYROIDISM BY THYROID TRANSPLANTATION.\*

BY  
ALBERT KOCHER, M.D.,  
BERNE.

It is to-day generally admitted by physicians and surgeons that transplantation of thyroid gland tissue, from man to man, or from animal to man, is not successful, and therefore most surgeons do not do it.

It is now forty-five years since my father, the late Professor Theodor Kocher of Berne, introduced this method and made some experiments with it. Since then there have been some successes and many failures. The failures are due, in my opinion, to insufficient technique, especially pre-operative and post-operative technique.

### Congenital Absence of Thyroid Gland.

We have, up to date, done 214 thyroid transplantations in man, and it is possible therefore to state the practical result, which is more important than any theory. Amongst the 214 there were about 10 cases of congenital total absence of thyroid gland; in these cases the results are, as a rule, not satisfactory, but 3 out of the 10 cases have benefited so much that they have been able to follow the school normally. One boy has even been able to take a university degree.

### Congenital Thyroid Insufficiency.

All the other 204 were cases of hypothyroidism, more or less severe. In such cases the thyroid gland is not absent, but there is greater or less degree of congenital insufficiency. In about half of the cases the condition is not diagnosed early in childhood, because distinct clinical symptoms occur only later in life, when the gland should work more, or when it has been hurt or overdone. Thus, distinct clinical symptoms appear at the age of development, after multiple pregnancies, in the menopause, or at the time when a goitre develops, or when chronic bacterial or toxic thyroiditis sets in, or, more especially, after severe general infections such as typhoid, influenza, dysentery, furunculosis, syphilis, tuberculosis, etc., and also after gynaecological operations, when the ovaries have been partially or totally removed.

Clinical symptoms and the methods of diagnosis of these cases were first described by Theodor Kocher in 1909, under the name of "Slight thyroid insufficiency." For diagnosis the method of choice is Kocher's functional thyroid test; it depends on the change in the white cells and coagulability of blood and the influence of thyroid feeding on it; basal metabolism is very little changed in these cases. Hypothyroidism is not yet sufficiently known; very often severe rheumatism, neuralgia, stomach, intestinal, and heart trouble of unknown origin are due to hypothyroidism and cured by transplantation of thyroid tissue. This is the method of choice in these cases, as thyroid feeding often causes stomach trouble and is never carried on long enough.

Of our 204 cases of hypothyroidism, 26 per cent. have been entirely cured by transplantation and have not taken any thyroid since; 21 per cent. have been very much better since and have to take only now and then a small quantity of thyroid, whilst before the transplantation they had to take continually much more thyroid and never felt so well; 39 per cent. are much better since the transplantation; they have to take thyroid internally, but only about one-half or one-third of the quantity they took before the transplantation. There were only 14 per cent. failures—that is, cases which did not benefit from the transplantation. There is no doubt that this result, in such a number of cases, proves that the transplant is active, at least for several years. In most of the cases the patient's own thyroid gland resumes normal function after some years and he is cured; if not another transplantation can be done. In twenty of our cases transplantation has been done twice and they got well in eight cases three, and in one four transplantations have been made.

In addition to these clinical results, I can produce dire evidence that the transplanted thyroid tissue takes up t

\*A paper read at the meeting of the International Society of Surgeons, London, 1923.

required of the student can usefully be expected of him within the years of his student course. Claims have of late years been put forward that in the final examination questions should be put upon various special branches of practice. Specialists have upheld the importance of their particular specialties, and have stated the dangers that ignorance of them involves. But the authorities have shown a tendency to answer that the student cannot be expected to know the prophets as well as the law, and that under present conditions some subjects must inevitably be left for special study after qualification.

This leads naturally to the question what effect the increasing subdivision of medicine and surgery has upon education. In some ways it is beneficial. No doubt a man who treats one organ or one class of diseases sees more examples of it and can study it more fully than one in more general practice. This is of advantage both for pathology and for treatment, and both patients and students reap the benefit. And since each organ or disease can afford examples of the wider laws of pathology, subdivision does not necessarily cramp the view of either teacher or student. Indeed, it may be argued that it improves it, for the student seeing, for instance, the effect of inflammation in various conditions which are clearly separated for him, gains perhaps a more distinct idea of the process than from a confused medley of cases. He can compare its effects in syphilis and tubercle, or see it exemplified in the skin and in nervous centres.

Yet there is a weakness in the present system to be set against its gains. In former times the hospital was more or less representative of ordinary practice. In the out-patient room and the wards taken together most of the problems were exemplified which would present themselves in later life, and, as in later life, they were presented unexpectedly. The patient might be suffering from almost any kind of disease, and the student had to keep his clinical knowledge ready and in constant use. He was expected to give a careful account of the patient's symptoms, and though in most cases he was not expected to form a diagnosis, yet he constantly endeavoured to do so, and in this way always practising himself in the same processes of thought as he would pursue in later life.

It is different now. He knows that when he is in the V.D. clinic he will see syphilis and gonorrhoea, and in the tuberculosis department cases of that disease, whereas he will hardly see a case of either in the rest of the hospital. He is not, therefore, as he used to be, continually on the look-out for these diseases in the general wards or in the out-patient room, and he is so much the less practised in diagnosis. In fact, to a considerable extent he postpones the practice of diagnosis to the time at which he enters upon an independent position, and finds that he is obliged to sort his patients for himself.

## IV.

In this matter there are two directly opposite opinions current among those who theorize upon education. British teaching placed diagnosis very high in the scale of medical duties. It was considered of the first necessity to find out what was the matter with the patient, and the student's mind was directed to this end throughout his examination of the case. It must not be thought that he was allowed to jump to conclusions. The very contrary was the fact. It was constantly impressed upon him that his examination must be as complete as possible, and his constant fear was lest his master should discover omissions in his notes and censure him for negligence, or, still worse, for forming an opinion without having taken the pains to guard it by sufficient observation. He was constantly warned that in practice more mistakes were due to want of observation than to want of skill, and the criticism of his teacher was invariably directed to the inaccuracy of his notes rather than to the incorrectness of his diagnosis. In so far as precept and example could, he was made to understand that the first requisite of a physician was accuracy in observation.

many cases judgment should be held in suspense, a diagnosis was the object to which observation was directed. His examinations and his notes were not made for the mere purpose of making them, but with this end in view. Not was it thought necessary, it must be allowed, to make a study of basic metabolism in every case of bronchitis, or that every observation that can possibly be made upon any case should be made upon all. There is, however, now current, especially in America, what may be called the encyclopaedic theory. Not the formation of judgment but its suspension is the function held most high. British teachers are criticized for training with a view to diagnosis instead of insisting on observation alone. Diagnosis itself is made a secondary thing, an object of distant hope, like a future life, but not a thing, thing to guide our action in the present. The first thing necessary is to make such a complete and detailed study of the patient's state that no cell remains untouched. That the world shall not contain the books (of notes) that shall be written is perhaps of little moment in a country that measures 1,500 by 3,000 miles; that before an exhaustive study such as this is finished both teacher and student may have sunk into the grave is not an obstacle in a population of a hundred millions, nor where it rains dollars need the cost be prohibitive. But it seems doubtful if in some cases the patient's untimely death may not render nugatory the incomplete though magnificent attempt.

Seriously, however, it is to be hoped that the British point of view may be maintained. On nothing has so much nonsense been said as on the subject of education, and on nothing are sensible men more prone to push their views to an excess which is ridiculous. Just at present the immense increase of our powers of observation has naturally led men to exaggerate its scope. We have indeed seen instances in which new light has been shed by phenomena which are usually insignificant, but that is not to say that such occurrences are common. It still remains true that in the great majority of cases we know the limits within which labours observation may be usefully employed. And while it is in thorough accord with our traditions to try observation to its fullest limit, yet it is our habit to try to make up our minds. It is often said that the British, or perhaps the English, are of a race that has no sympathy with principle and is are of a race that has no sympathy with principle and is interested in action alone; that they are efficient in difficulties but can give no reason why; that the Constitution have tumbled into an empire which will perhaps continue by good luck but certainly not by good management. That is a complete misreading of the English character. The real feeling which shapes English thought—and thought is universal, and we doubt whether all conclusions are not than some are—but we know that it is unsatisfactory and uncertain, and we take a provisional conclusion and act upon it—perhaps we are readier in making such quick judgments have a haunting feeling that we have never observed the a logical basis for action as much as other races, but we present to us most vividly throughout our lives. We desire immensity and the immensity of the unknown. This is always and in all men moulded by feeling—is a sense of the real feeling which shapes English thought—and thought is universal, and we doubt whether all conclusions are not than some are—but we know that it is unsatisfactory and uncertain, and we take a provisional conclusion and act upon it—perhaps we are readier in making such quick judgments have a haunting feeling that we have never observed the

With this gentleness and cast of mind our critics may be sure with us, and truth seems very far away. Probably unisoned. Few general laws command respect whose basis, from the fallacy of insufficient instances, is action unsafe, because they are deduced from principles of the same. We are apt to think logical rules of unerring, and we doubt whether all conclusions are not than some are—but we know that it is unsatisfactory and uncertain, and we take a provisional conclusion and act upon it—perhaps we are readier in making such quick judgments have a haunting feeling that we have never observed the a logical basis for action as much as other races, but we present to us most vividly throughout our lives. responsible. The same applies to tonsillar infection, which, though not so obvious as pyorrhoea and therefore less frequently recognized, is one of the maladies to which most men are heir, and therefore again this cannot be held to be the only factor in the etiology of rheumatoid arthritis.

In almost all cases of the group under discussion there is a history of dyspepsia, which takes the form of anorexia, flatulence, and constipation, the last being a constant feature; but it is unusual to discover any local focus in connexion with the intestinal tract, such as an obviously inflamed gall bladder or appendix. The exact etiology of rheumatoid arthritis, therefore, must remain obscure until such time as the nature of the "soil" has been more fully investigated, when recognition of the type or types of "seed" concerned in the production of the disease should present less difficulty.

#### CLINICAL FEATURES.

The predominant feature of rheumatoid arthritis and the one for which the patient seeks advice is the swelling and pain of the joints. The first to be affected are usually the small distal joints, especially of the upper limb. It is characteristic of the early cases to show swelling of the second or second and third metacarpo-phalangeal joints, with pain and slight swelling of the wrist, which precedes ulnar deviation; one or more of the mid-phalangeal joints are often involved and show the characteristic spindle shape. In the later stages the larger joints may be affected, the disease sometimes spreading from joint to joint throughout the body. A symmetrical distribution characterizes the progress of the disease.

The morbid process chiefly affects the synovial membrane and ligamentous structures round the joint, and although this is swollen it is rare that fluid can be extracted in any quantity. That the pathological involvement is not confined to these parts is shown, however, by the changes in bone structure as disclosed by x-ray photographs. These changes consist chiefly of rarefaction in the neighbourhood of joint surfaces. It is, indeed, remarkable in late cases with most marked deformities how slight are the osseous changes. As the disease advances the ligaments become much relaxed, with resulting ulnar deviation of fingers and wrist and valgus deformities of the toes and complete flat-foot. In the same way the larger joints, though showing less deformity in the absence of muscular contractures, become markedly unstable, and lateral mobility of the knees is very noticeable.

That the joints are not the only manifestation of the disease is apparent. There would seem to be a general metabolic upset involving the endocrine glands. Clinically there are many signs suggestive of hyperthyroidism. Excessive sweating, fibrillary twitchings, a tendency to disordered action of the heart, and overbrisk tendon reflexes are met with, and there is often that nervous instability and apprehensiveness which is associated with disordered endocrine function. The vasomotor system is markedly upset, with flushing and even dermatographia; or a condition of the extremities approaching Raynaud's disease may be found. The skin shows trophic changes, comprising loss of subcutaneous fat and a glazed appearance with loss of hair. The muscular wasting is early and pronounced and more than can be accounted for by the disuse of a limb consequent on the joint condition. It is this wasting, especially of the intrinsic muscles and subcutaneous fat of the hands, that emphasizes the characteristic spindle appearance of the joints.

If careful examination is made in the region of the joint, enlargement of the lymphatic glands can be detected. Inasmuch as the hands are earliest and most severely affected the glands most definitely involved are the epitrochlear, but axillary, femoral, and inguinal are also found enlarged. In 20 cases showing a clinical joint picture as described above all showed enlargement of glands.

The blood picture presents characteristic changes in the majority of cases. Secondary anaemia is common, but by no means universally severe, and a slight or moderate leucocytosis is often met with. The importance of the total white count, which may vary in the course of the disease, is overshadowed by that of the differential, which shows a

definite increase in the small mononuclear cells relative to the polymorphonuclears. This feature, however, is only important in conjunction with the other clinical signs, as it is met with in many other forms of arthritis. In 19 cases examined out of the 20 cases mentioned above, all showed a relative increase in small mononuclears. In certain cases the spleen is found to be palpable, but this is never excessive and by no means constant.

Examination of the gastric contents shows absence or diminution of free hydrochloric acid in the majority of cases, and this, in our opinion, is frequently the crucial factor in the whole clinical picture. Thus, in the 20 cases examined, 14 had complete achlorhydria, one a trace of free hydrochloric acid only, 2 marked diminution, while 3 were normal. The test used was Ewald's test meal.

#### COURSE OF THE DISEASE.

The onset is usually between the ages of 20 and 30, though cases commencing in the adjacent decades are by no means uncommon. It should be noted that this excludes cases of Still's disease, which is presumably rheumatoid arthritis in children. The course is prolonged, extending over years.

Initially there is often a period of pyrexia, the temperature swinging up to 101° or 102°, but not usually higher. This may recur during the succeeding years for a few weeks at a time for no very obvious reason after long periods of remission. The active inflammatory condition may spread from joint to joint, dying out of some and affecting others, and eventually there is a tendency for the condition to die out altogether, often leaving behind it severely deformed joints and (if care is not taken in the management of the case) serious contractures and ankyloses in bad positions.

#### THEORETICAL CONCLUSIONS.

It is admitted that not nearly enough observations have been carried out to warrant definite conclusions on this clinical group; but this only purports to be a preliminary communication, and it is hoped to carry out further investigations to confirm or modify the views expressed above. Considerable work has already been done on the subject of achlorhydria by Hurst and his collaborators<sup>2</sup> at Guy's Hospital, especially in connexion with Addison's anaemia and subacute combined degeneration of the spinal cord. First they have shown that achlorhydria may be apparently congenital, for in 4 per cent. of perfectly healthy young men without digestive symptoms this condition was found. Hurst further concludes that the achlorhydria precedes not only the anaemic conditions in which it is so frequently discovered, but also those cases of chronic gastritis which formerly were supposed to be the cause of the achylia. The gastritis is due to the failure of the normal softening and diluting action of the juice, and as the food is not sufficiently digested in the stomach it will irritate the intestine in the same way and cause intestinal dyspepsia. At the same time proteins will reach the small and large intestines unchanged, and with them numerous bacteria which would normally be destroyed by the acid disinfecting properties of the gastric juice. The decomposition of the proteins by these bacteria produces further irritative material which modifies the absorption of toxins. Hurst<sup>3</sup> mentions the presence of achylia gastrica in rheumatoid arthritis; Woodwark and Mackenzie Wallis<sup>4</sup> have described diminution or absence of free HCl in 9 out of 10 cases; and Faber<sup>5</sup> has described free HCl in 15 out of 65 patients suffering from achylia gastrica in chronic polyarthritis. In our view, however, it is probable that this polyarthritis included joint conditions other than that group which we are attempting to differentiate, and that if the observations were confined to those cases showing that if the observations were confined to those cases showing joints of the typical kind and distribution with glandular enlargement and lymphocytosis, then a much higher percentage of achlorhydria would be found.

In discussing the pathogenesis of subacute combined degeneration and Addison's anaemia, Hurst<sup>6</sup> suggests that the passage of the *Streptococcus longus* from infected teeth and gums through the stomach into the large intestine, owing to the absence of free hydrochloric acid, produces various toxins either from their own activity or from the breaking down of undigested proteins. He suggests that the incidence of anaemia or subacute combined degeneration

£10,000; total 13,500,000. The approximate number of insured persons on the lists of insurance practitioners was in England 11,500,000; in Wales 733,600; total 12,233,600. In addition, there were 139,000 insured persons on the lists of approved institutions (England and Wales 29,000), and 11,800 insured persons (England and Wales 11,800) made their own arrangements for medical treatment. "The number of insurance practitioners in 1922 was in England 11,750, and in Wales 233, a total of 12,558. Fifty per cent. of the doctors have under 300 persons on their panel, and 65 per cent. under 2,000. The average is 1,000."

The report contains a reference to disciplinary cases, and Sir George Newman takes the opportunity of pointing out that the complaints occurred in the course of the treatment of at least six million insured persons and of forty-four million attendances.

*Sickness and Invalidity.*

In 1922, the total loss of work, as represented by payments under the Act, amounted to 19½ million weeks, or 375,000 years. In addition, there was all the sickness which did not involve loss of work, and all the labour and expenditure in the care of the sick. In 1,000 cases of incapacity, the chief causes were bronchitis, catarrh, cold, etc. 213, digestive diseases 151, lumbago, rheumatism, etc. 88, influenza 85, injuries and accidents 79, abscesses, boils, and other septic conditions 69, debility, neuralgia, and headache 55, nervous and special sense diseases 49, skin diseases 49, anaemia 32, genito-urinary diseases 25, pneumonia and other respiratory diseases 15, organic heart disease 14, tuberculosis 14, and malignant disease 2; leaving a balance of about 81 due to other causes.

*Poor Law Medical Service.*

Certain proposals to transfer infants and young children from an institution to more pleasant surroundings in the country have been approved. The system of appointing medical consultants at Poor Law infirmaries is being extended, and in London only three or four infirmaries are now without them. These institutions are approximating more and more to the standard of general hospitals, and they are being used more and more for medical education. The statistics of notifiable infectious diseases presented no unusual features, except that a considerable decline occurred in the group having a peculiar affinity with the nervous system—encephalitis lethargica and the rest.

*Small-pox.*

The story of small-pox in England in 1922 and subsequently has been told in the medical press throughout the year in connection with prevalence of the disease in different districts, and Sir William Hamer has given an account of the disease in London. It is convenient now to have it set forth for the whole of England and Wales, but it has been dealt with so fully in this *Journal* that it need not be again gone over. As usual the facts clearly and convincingly teach to all who are capable of learning and are willing to learn the preventability and controllability of the infection by due resort to the prophylactic whose virtue Jenner published to the world at the end of the eighteenth century. Vaccination has stood the test of more than 120 years' outbreak. Sir George Newman, in his summing up of "the present situation," reiterates briefly and forcibly essential truths to which there is no reply.

*Measles.*

Measles, it is pointed out, remains one of our formidable enemies, but the average number of annual deaths during the past three years (5,642) was considerably less than the average (7,318) for the preceding four years, in which the disease was compulsorily notifiable throughout the whole country. The problems relating to measles are discussed in considerable detail in the report, with reference in particular to the practicability of postexposure of epidemics, and the segregation, discovery, and control of contacts. When the disease has already spread, attention should be devoted to prevention of mortality and of complications or sequelae. The report gives a full account of the measures or

The recurrence of influenza in the latter part of 1921 reached a maximum by the end of January, 1922, and then declined. It was accompanied by increased notification of pneumonia. In Sheffield there was a genuine epidemic of pneumonia, and as that city has excellent accommodation for pneumonia, every effort was made, with the able assistance of the local Division of the British Medical Association, to secure complete notification, so that when the Ministry's representative visited in July not a single death. Leeds and Bradford were also considerably affected. The total number of deaths from influenza in England and Wales in 1922 was 21,498.

*Epidemic Nervous Diseases.*

Polio-myelitis, poli-encephalitis, cerebro-spinal fever, and encephalitis lethargica are considered together as in previous years. From each of the four the deaths were fewer than in 1921, notably so in the case of encephalitis lethargica, for which the figure is 454 against 1,470, whilst from all four the total deaths have declined from 2,420 to 1,184.

Of encephalitis lethargica, however, it is remarked that "in addition to a high fatality, this disease leaves many patients grievously incapacitated by various neuropathic and psychopathic conditions," and that its late effects will need close attention in the future. Special inquiries are being continued, and an account is given of an investigation by Dr. Parsons and Dr. Ryle, of the Warwickshire Health Department, of a grouping of cases in the Warwickshire

*Diphtheria.*

The inquiries referred to in last year's report are being continued. The observations then recorded are confirmed to the effect that free swabbing should be resorted to in diagnosing a first outbreak of sore throat in an institution or school, but that promptaneous swabbing subsequent to previous becoming certain is of little use, and notifications depending solely on extensive swabbing have little justification. An official memorandum issued in July, 1922, dealt with the supply and administration of diphtheria antitoxin, the use of the Schick test, and methods of active immunization. The International Serological Conference has made the useful proposal that a standard anti-toxin should be maintained at the State Serum Institute at Copenhagen, to which manufacturers can send specimens for comparison.

Under the guidance of Dr. Copeman much work has been made of the Schick test as a means of estimating individual susceptibility to diphtheria as in the West Norwood schools of the Lambeth Guardians, and in the case of nurses and others in close attendance on diphtheria. The results seem to indicate lower percentages of susceptibility among classes where some degree of immunity may have been acquired through unrecognized exposure to infection. As regards toxin-antitoxin immunization, Dr. Copeman has concluded that to avoid risk of severe reaction, especially in adults and individuals liable to "serum rash," an exceptionally small dose should be given at first, to be followed by an ordinary dose if there is no unusual reaction within twenty-four hours of the small dose.

Scarlet fever is being carefully studied by the Ministry in respect of the whole subject of its control, looking to mildness of type in modern times, to the high cost of lengthened institutional segregation and of disinfection, and to the practicability of safe home treatment as at present being carried out in the Tottenham Urban District. The result of the investigation will be awaited with interest.

*Scarlet Fever.*

Protective comparable to vaccination is yet available, resembles pre-vaccination small-pox in the fact that no where locally converted desirable. Measles unfortunately in connection with child welfare, and compulsory notification breaks in institutions. Government grants for measles work national and convalescent home treatment, after-care, out-

I gave her two injections (1.5 c.cm. and 2 c.cm.) at an interval of seven days. The rash disappeared and she has been quite free since.

## CASE II.

A married woman, aged 21, had suffered from regular attacks of urticaria all over the body, but more pronounced where the clothing was tight (waist, etc.), for nine months. When I first saw her she had a typical urticarial rash on the legs, arms, chest, and round the waist, and at that time any scratching or irritation brought out fresh wheals. She was in a highly excited and nervous condition. I gave her 0.5 c.cm. colloidal manganese by intramuscular injection. On her return at the end of a week she was much better and reported that the rash had only appeared on two occasions during the interval. I gave her another injection of 0.5 c.cm. At the end of the second week she was decidedly better. I gave her four more injections (1 c.cm., 1.5 c.cm., 1.5 c.cm., and 2 c.cm.) at weekly intervals, and at the end of six weeks the symptoms had entirely disappeared. Twelve months after the completion of the treatment she reported herself as being quite well.

## CASE III.

A married woman, aged 29. This case was more intractable; after six injections as above described the symptoms still continued, but with less violence. I gave her four more injections (1.5 c.cm.) at intervals of two weeks, and at the end of eight weeks there was no evidence of the rash. After an interval of fourteen months she writes to say that there has been no recurrence.

## CASE IV.

A man, aged 18, had been troubled with "nettle rash" for several months. I gave him four weekly injections (1 c.cm., 1 c.cm., 1.5 c.cm., 1.5 c.cm.) by intramuscular injection. At the end of the fourth week he was quite free and the treatment was discontinued.

Since treating the above cases several others have received the same treatment with marked success, but sufficient time has not yet elapsed to include them in statistics.

## VACCINATION PROPAGANDA AND THE MEDICAL PROFESSION.

BY

C. KILLICK MILLARD, M.D., D.Sc.,  
MEDICAL OFFICER OF HEALTH, LEICESTER.

THERE have been several suggestions recently that the "conscience clause" of the 1898 Vaccination Act should be repealed and compulsory vaccination enforced more uncompromisingly. A suggestion has also been made by a correspondent of the *BRITISH MEDICAL JOURNAL* (July 21st, p. 130) that an active propaganda in favour of vaccination should be launched, with the special object of depicting the horrors of small-pox graphically on mural posters.

It is doubtful if the provaccinist "die-hards" who favour these suggestions quite appreciate what a change has taken place as regards the "vaccination question" during recent years. Whether we like it or not we have got to face the fact that the logic of events has told heavily against the provaccinist position (in some of its aspects at least) and in favour of the antivaccinists.

Infantile vaccination reached its maximum in this country in 1881, when the vaccination figure, expressed as a percentage of the births, was 86.6. Since then it has fallen continuously until in 1921 it was only 38.3. Ever since this decline set in we, as a profession, have taken almost every opportunity, in season and out of season, to warn the public of what we sincerely believed would be the inevitable consequences of this neglect of vaccination—namely, an increase, and a serious increase, in small-pox mortality. When the "conscience clause" was proposed, as a result of the Royal Commission's report, we opposed it for all we were worth. We said it would result in a further neglect of vaccination, and we declined to accept any responsibility for the consequences. At that time we may be said to have "shot our bolt," and the bolt has failed. The "conscience clause" was passed, a further and serious decrease in vaccination followed, but instead of any increase in small-pox mortality it has continued to fall. It is true there was a slight increase for a couple of years, in 1902-3, but since then it has not merely fallen—it has collapsed. For the past seventeen years in this country small-pox mortality has been a negligible quantity. It has caused fewer deaths than almost any other zymotic disease. Even chicken-pox, most despised of zymotics, has caused

1,277 deaths in the sixteen years 1906-20, against only 223 from small-pox, and if we deduct small-pox deaths in vaccinated subjects the contrast would be still more striking. Why, even the registered deaths from vaccinia amounted to 165, and it has recently been admitted, in answer to a question in Parliament, that by no means all the deaths due to sepsis following vaccination are debited by the Registrar-General to vaccinia.

The medical profession has kept saying: "Only wait! Have a little patience and Nemesis will surely come!" But the years pass and Nemesis does not come. Ten years after the city of Leicester, in spite of all medical warnings, had openly set the Vaccination Acts at defiance, an epidemic of small-pox did occur (in 1893), but it was a damp squib, not at all what had been prophesied. Ten years later, in 1903, came another epidemic; again it was a damp squib—certainly not Nemesis. For the past eighteen years there has not been a single death from small-pox in Leicester. And now comes Gloucester, a city almost as notorious as a centre of antivaccination as Leicester. No one will deny that every effort was exerted to make the most of the recent Gloucester epidemic. Everything that press publicity could do to magnify the seriousness of the outbreak and bring home to the public the heinousness of neglecting vaccination was done. Yet instead of a dreadful object lesson the cases have been so extremely, almost absurdly, mild that great difficulty was experienced in persuading the people that this really was small-pox, of the horrors of which they had heard so much. One little baby, six weeks old, was the only victim who has succumbed to it. Surely it is a case of the mountain in labour!

The most regrettable thing about the epidemic, from the medical point of view, is that there ought never to have been an epidemic at all, but for the unfortunate failure of members of our own profession to recognize the true nature of the disease. Once it was recognized and modern measures of prevention, particularly isolation in hospital, put in operation, the outbreak quickly subsided. Yet this is the time when the die-hards would agitate for provaccinist legislation and embark on propaganda. Surely we must show some sense of proportion if we would retain the respect and confidence of the public, which looks to us for advice and guidance.

I recognize and admit, in spite of the fact that small-pox mortality has been declining in this country for the past fifty years, that at some future time it may return. So may that of any other zymotic disease that has disappeared or is disappearing since the advent of the sanitary era. But happily in the case of small-pox we possess a "talisman" which we do not possess in the case of any other disease. I refer, of course, to recent vaccination, to be performed if the need for it should ever arise, and which for me robs small-pox of much of the terror which it seems to inspire in so many other medical men.

To prevent misapprehension let me say that it is not vaccination which is at fault to-day, but rather, as I suggest, our method of using and applying it. The power of vaccination to confer temporary immunity against small-pox upon the individual is still as certain to-day as any fact in the whole field of medicine. But I venture also to say that the case for compulsory infant vaccination as a measure for protecting the community has never been weaker. I suggest that it rests on a very shaky foundation, and that it is only a question of time before this country will follow the example of the State of New York and see the wisdom of entirely abolishing compulsory vaccination. Those who believe in infant vaccination will still be able to have their children vaccinated, and those who object to vaccination will please themselves. When that time comes this unhappy controversy, which has aroused so many bad passions, wasted so much printer's ink, taken up so much valuable time of the Minister of Health in answering questions in Parliament, and done more than anything else to bring our profession into disrepute, will no doubt die a natural death from inanition. Prejudice against opposition to vaccination will follow suit from lack of food to feed on, and if and when virulent small-pox returns, and the need for recent vaccination arises, it will be far easier, I submit, to persuade people to be vaccinated.

different strains of diphtheria bacilli. Routine work included preparation of antitoxic vaccine, examination of food materials for *B. botulinus*, examination of shavings, brushes, etc., for anthrax, examination of specimens from cases of suspected infectious disease, of Grade A milk, and of food samples. The Auxiliary Scientific Investigation Unit was spent on special work relating to public health, as on Wassermann tests in the newborn, study of the Schick test, and of mosquito life. Liaison with the Medical Research Council was maintained, partly by membership of special committees. Statistical investigations of various sorts were conducted, and many questions of interpretation of data, etc., dealt with. Epidemiological inquiries have already been mentioned.

#### Miscellaneous.

The Interdepartmental Committee on Rheumatism, of which Sir George Buchanan is chairman, began by making an estimate of the respective incidence of the various forms of "rheumatic" diseases in relation to age, sex, occupation, and environment. A large team of insurance practitioners entered with zest into the scheme. "Fifty practitioners fulfilled for the whole year the arduous task of recording, on a uniform plan, every case of rheumatic disease occurring in an insured person in their practices," and a population of 50,000 insured persons has been in this way kept under review. This is the first group inquiry on these lines, and a great advantage is that the population at risk, represented by this sample, is fairly accurately known. The regional medical officers have made inquiry on the same plan as regards 5,000 cases referred to them. The rheumatic diseases were classified under nine headings, and these were placed in three groups—(1) acute, (2) non-articular, and (3) chronic joint change.

#### Gout.

The causation and prevention of gout, as it occurs in widely separated districts of England, have been studied. The simultaneous occurrence of enlarged thyroid in a number of children at cottage homes was carefully investigated by Dr. Adams. Other subjects of investigation were an outbreak of "pink-eye" amongst school children at a college, the dermatitis of bakers—so-called "bakers' itch"—and alleged tetraethylchlorthane poisoning in toilet saloons.

### KITCHENER MEMORIAL MEDICAL SCHOOL AT KHARTOUM.

O. F. H. ATKIN, M.B., B.S. LOND., F.R.C.S. (ENG.),  
DIRECTOR, MEDICAL DEPARTMENT, SDP.

The object of the Kitchener Memorial Medical School is to provide a sound medical training for young Sudan Arabs, so as to meet the large demand for doctors which at present exists and which is likely to increase very greatly during the next few years as the schemes at present in hand for the economic development of the Sudan come into action and are gradually extended. The need for this school was first urged by Lord Kitchener during his last visit to the Sudan; he looked on it as the most important step in the completion of the educational scheme which he initiated when he founded the Gordon Memorial College. The foresight and imagination shown by Lord Kitchener in founding this college immediately after the battle of Omdurman at a time when over three-quarters of the population had died from famine and disease, and the land was deserted and uncultivated, has been more than justified by results. The recovery of the Sudan has been phenomenal and it could not have taken place without the agency of this institution. The Sudanese, with the exception of the inhabitants of the extreme south, are an Arab race differing from the Egyptians in physical characteristics, in ideals, history, and origin; they are quick, intelligent, eager for education, and

Small-pox as an infection introduced from abroad is reported on thus:

"A noteworthy feature of the small-pox statistics received from abroad is the evidence which they provide of the respective incidence of the mild type and of the severe type of the disease. The statistics available indicate that in 1922 the mild non-fatal type was the rule in Finland, Germany, Switzerland, Egypt, Cuba, Jamaica, South Africa and parts of Central and South America. In a few countries (notably Ontario) the mild type prevailed during the early months of the year was followed, after an interval, by an epidemic of the severe type, and in one or two (as in Portugal and England) where both types appeared during the year, it was found that the two seemed to run concurrently, some localities experiencing only the mild type, others only the severe type."

Among the 729 cases in England in 1922 were included a large proportion of instances of relapsing amoebic dysentery among ex-service men. In Wales there was an outbreak of 1,100 cases of bacillary dysentery, with low mortality. It was conveyed at first by contaminated water, and the infection may have been derived from demobilized soldiers.

#### French Fever.

Only 6 cases of trench fever were reported—all ex-service men.

#### Yellow Fever.

The position as to yellow fever seems favourable, though it persists in various localities in South and Central America, including Mexico.

#### Typhus.

The prevalence of typhus fever in Russia seems to have doubled in the first five months of 1922. It is, however, a house-carried disease against which organized sanitary administration is effective if the simultaneous arrival of large numbers of infected persons can be avoided. From this point of view the preventive work carried on in the border States of Russia with the aid of the League of Nations is of great importance. The need for the control of destitute immigrants from infected areas is exemplified in the emigration of Greeks from Anatolia and Eastern Thrace.

#### Medical Intelligence.

The Intelligence Division of the Ministry is organized in two sections, lay and medical. Information is collected from home and foreign sources and distributed. Recent information published in books and journals is noted. Prompt and regular news of the incidence of dangerous epidemic diseases at ports and elsewhere abroad is collected, and a weekly bulletin issued to health officers and others specially concerned. In 1922 information was received from 170 consuls or other official representatives abroad, and 5,248 telegrams or dispatches were received, besides many printed statistical returns. Office committees were formed to investigate questions relating to scarlet fever, rheumatism, and grand-child public health expenditure. International health work is notably developing, bringing the Ministry's medical officers into touch with their colleagues in foreign countries, the British Dominions and Colonies, India, and Egypt. The maintenance of a health organization will, in future, form part of the permanent functions of the League of Nations. The work done can be studied in the publications of the Office International d'Hygiène Publique. Progress has been made with the international agreement for treatment of venereal disease in merchant seamen, and additional countries are falling in with the scheme. Contributions from the Rockefeller Foundation have helped further development in intelligence work and health statistics, and have also helped to make possible such an educational visit as was paid to this country last year by about thirty medical officers from different foreign countries.

#### INVESTIGATION AND RESEARCH.

Work at the Ministry's laboratories related to pneumococcus and investigations into the serological characters of

the author has excised in four cases. Carcinoma developing from the duodenal mucosa is to be distinguished from that of the ampulla itself; the former tends to invade the bowel circularly, the latter shows little disposition to extend or to invade the neighbouring parts, and may for long, and even to the time of death, remain limited to the ampulla. In removing the growth the transduodenal route is usually adopted. In many cases the tumour has been removed without incising the whole thickness of the duodenal wall; in others it has been necessary to perform a transverse resection. The author refers to 32 cases, with 14 deaths. The after-histories were obtained in 11 cases; recurrence took place in 6 in from three months to two and a half years; 5 were in perfect health after eight months, two years, four years, six years, and nine years. Reference is made to a case under Abell which was treated with radium after duodenotomy; the final result is not stated. The value of the book is greatly enhanced by the large number of fully reported cases.

### THE CLASSIFICATION OF TUMOURS.

PROFESSOR MASSON'S work on tumours and histological diagnosis forms part of the twenty-seventh volume of the *Traité de Pathologie Médicale*,<sup>2</sup> published under the direction of Professor Sergeant. The work is divided into three parts, dealing with the theoretical study of tumours, the concrete study of tumours, and laboratory technique. Tumours are defined as purely cellular or tissue formations, the essential character of which is the proliferation of the cells of a definite region, producing masses that persist and live as parasites on the organism. They are primarily classified as (1) dysgenetic, constituted of tissues normal in themselves but abnormally situated; (2) hyperplastic, due to a definite irritant external to the cells themselves; and (3) neoplastic, composed of cells possessing a newly acquired, indefinite, and autonomous fertility, and simple or malignant in their action. The three classes are, therefore, distinguished by their cellular fertility, which is embryonic in the first, irritative in the second, and inherent and autonomous in the third.

In treating of dysgenetic tumours the whole subject of heterotopy is discussed, including grafts and transplantations, vestigial rests, traumatic inclusions, and dys-embryomas. The last named may be total, arising from cells capable of producing any tissue of the body (teratoma); regional or partial, arising from somewhat more differentiated cells; or simple, arising from fully differentiated cells of one type. None of the tumours classed as dysgenetic are to be regarded as neoplasms, but they may become neoplastic.

In dealing with hyperplastic tumours it becomes necessary to study the reaction of the tissues to external irritants, and a chapter is accordingly devoted to acute and chronic inflammation, simple and specific, and to tissue repair; metaplasia is also considered in this connexion. As bearing on the nomenclature of tumours the author adopts the view that a cell is characterized by its function and not by its blastodermic origin; an epithelial cell which assumes the property of secreting collagen or chondrin thereby becomes a connective tissue or cartilage cell. On this view, for instance, adrenal growths are properly placed among epithelial tumours. On the other hand, meningeal tumours present some difficulty; the meninges are believed to arise by migration of cells of nervous origin, which take on the characters of mesodermal cells, so that the membranes have some analogy to the sheath of Schwann. Masson, for this reason, excludes meningeal tumours from the connective tissue group. The name "meningoblastoma" has been suggested for them, and is adopted by the author.

In the second part of the book, dealing with the concrete study of tumours, the different tissues and organs are taken in order, and described on the basis of the classification above mentioned, and this, the principal part

of the work, has been carried out with great completeness, and the accompanying illustrations are good. The author deplors the lack of interest shown in pathological anatomy in France at the present time, and claims that the status of the pathological anatomist as a specialist should receive more recognition. He insists on the importance of histology in medical diagnosis, but on one condition—namely, that it is in the hands of specialists. But specialists cannot be had unless they are able to live, and Masson closes his work with the remark, "l'histologiste doit être payé en raison des services qu'il rend."

### CANCER OF THE OESOPHAGUS.

M. JEAN GUISEZ has been practising oesophagoscopy for twenty years; the total number of examinations he has made exceeds 2,500; the knowledge he has acquired is considerable. It is this knowledge, derived mostly from his own observations and the inferences he has drawn from them, that is embodied in his book on strictures of the oesophagus and trachea.<sup>3</sup> The greater part—about five-sixths—is devoted to the oesophagus; the section on the trachea and bronchi occupies only about fifty pages at the end. He adopts the usual classification of strictures into the intrinsic and extrinsic varieties. It is interesting to note that in his experience more than two-thirds of the intrinsic strictures of the oesophagus are due to cancer. On this subject he is peculiarly illuminating. For instance, he has observed that in about 70 per cent. of these cases there has been an element of personal grief, following some domestic or financial loss. He is inclined to the belief that worry so caused gives rise to a spasmodic stricture, which in its turn is followed by stasis and oesophagitis, the latter preceding the onset of a malignant growth. Whether the first part of this sequence is correct it is difficult to say, but there seems to be little doubt about the truth of the second part—the connexion between inflammation and cancer. Over and over again he has seen an epitheliomatous patch grafted on the wall of an inflamed portion of the oesophagus—an experience that but confirms the findings of others.

With regard to the treatment of oesophageal cancer his opinion of surgical intervention is not very high. His own successes have resulted chiefly from the use of radium. In the space of thirteen years he has treated 170 cases of cancer by the local application of this substance. The diagnosis was verified by biopsy. In 92 of these a cure was apparently effected. In 18 of them the cure has been maintained both clinically and oesophagoscopically over a period varying from one to eleven years. These results are distinctly favourable and lend hope for a further extension in the adoption of this treatment. The book is very well illustrated, and is so full of personal observations that it has all the charm that attends originality. It will be welcomed as heartily in this country as in France.

### BLOOD SUGAR.

A CAREFUL and painstaking study of the blood sugar in normal and diabetic subjects is presented in the form of a monograph by K. M. HANSEN.<sup>4</sup> The problems investigated are, in general, familiar to workers in this field, and centre round the variations in blood sugar induced by fasting and by the administration of carbohydrate.

The treatise is divided into three sections. The first deals with the oscillations in the concentration of blood sugar in normal and diabetic individuals. If determinations of the blood sugar are made at frequent intervals after the ingestion of glucose, it is found that the curve does not rise smoothly but in a succession of waves or oscillations, and in fasting persons the fall of the blood sugar occurs in a similar fashion. This phenomenon is exhibited by both normal and diabetic subjects and is

## England and Wales.

Post-graduate lectures will be given by the honorary staff of the Manchester Royal Infirmary in medicine, surgery, and special subjects each week on Tuesday, from October 2nd till December 18th. The courses will be resumed on January 29th, 1934. Short courses explaining recent scientific work will also be given on Fridays from October 5th to December 7th. The first lecture, on October 2nd, will be by Dr. F. E. Tyteler, who will discuss some recent abdominal cases. On Friday, October 5th, Dr. Jackson S. Dunn will lecture on the regional diagnosis of paralytic. All the lectures will begin at 4.15 p.m. and will be free. Details can be obtained from the Secretary for the Post-graduate Lectures, at the Infirmary.

The post-graduate courses of the Clinical School of the University of Liverpool will be resumed on Monday, October 1st. The hospitals included in the scheme are the Royal Infirmary, the Stanley Hospital, the Royal Liverpool Children's Hospital, and the Hospital for Women in Shaw Street. The lectures and demonstrations will be largely clinical in character and will be given in the various hospitals in rotation, beginning with the Children's Hospital, where Dr. Fordyce will open the course with a lecture on glycosuria; at the Southern Hospital on the following day Mr. Douglas-Crawford will lecture on surgical lesions of the jaw; on Wednesday, at the Northern Hospital, Dr. Bigham will describe types of mental defects in children; on Thursday, at the Stanley Hospital, Dr. Gillian will speak on diseases of the endocrine organs; and on Friday, Dr. Abram will give a demonstration on clinical medicine at the Royal Infirmary. Further particulars and a card diary for the term can be obtained from Mr. J. C. Martineau, M.C., Secretary of the Clinical School, 61, Rodney Street, Liverpool. No fees will be charged.

In London post-graduate courses in various specialties, arranged by the Fellowship of Medicine and Post-Graduate Medical Association, will be given during the month of October. A course on urology at St. Peter's Hospital for Stone will begin on Monday, October 1st. Demonstrations will be given in the out-patient department every afternoon, and in addition lecture-demonstrations by members of the staff at 2 p.m., four times a week. A course of eight lectures given by Dr. Low and Dr. Manson-Bahr at the London School of Tropical Medicine, beginning on Tuesday, October 2nd. A course in laryngology, rhinology, and otology will be held at the Central London Throat, Nose, and Ear Hospital from October 8th to 26th; clinical lectures and demonstrations will be given by members of the staff each day from 9.30 to 5. A course on children's diseases will be given at the Victoria Hospital for Children from October 8th to November 3rd, and special clinical instruction in ophthalmology will be available at the Royal London Ophthalmic Hospital during the whole of the month. From October 15th to 27th short intensive courses in cardiology and proctology will be given at the National Hospital for Diseases of the Heart and St. Mark's Hospital respectively. A short course in dermatology will also be held at the Hospital for Diseases of the Skin, Blackfriars, from October 29th to November 10th, and a fortnight's "refresher" course in general medicine and surgery from November 5th to 17th. Copies of the syllabus and full particulars as to fees can be obtained from the Secretary to the Fellowship of Medicine at 1, Wimpole Street, W.1, and, as in some cases the numbers are limited, early application should be made.

### The British Association in Liverpool.

On Sunday, September 16th, in the Lady Chapel of the Cathedral, the Rev. E. W. Barnes, Canon Residentiary of Westminster, preached to a full congregation, and afterwards the Bishop of Liverpool gave briefly, in the almost completed choir of the cathedral, the story of its foundation and progress. Sir Oliver Lodge spoke from the pulpit of St. James' Church, and the Rev. J. H. W. Jones, Canon of the Cathedral, gave the address of welcome.

The concluding general meeting was held in St. George's Hall on September 19th. Sir E. Rutherford proposed from the chair a resolution expressing the warmest thanks and appreciation of the Association for the generosity and hospitality of the city of Liverpool had shown to the Association. The Lord Mayor, in accepting the resolution on behalf of the city, said that this, the 51st meeting, was the third largest in the history of the Association. The total membership of 3,256 was only about 500 short of the home-record held by Manchester.

The concluding general meeting was held in St. George's Hall on September 19th. Sir E. Rutherford proposed from the chair a resolution expressing the warmest thanks and appreciation of the Association for the generosity and hospitality of the city of Liverpool had shown to the Association. The Lord Mayor, in accepting the resolution on behalf of the city, said that this, the 51st meeting, was the third largest in the history of the Association. The total membership of 3,256 was only about 500 short of the home-record held by Manchester.

On September 18th the National Temperance League gave a luncheon, which was attended by the President of the Association, Sir Ernest Rutherford, Sir Richard Gregory, Bishop Weir, Mr. Bickerton, and after the luncheon Dr. John Hay delivered an excellent address on the scientific value of alcohol and embodied in his remarks the results of recent research. He mentioned the great national experiment of prohibition that was being carried out in the United States, and urged the importance of weighing the evidence in order to reach sound conclusions. Sir E. Rutherford agreed that prohibition in America should be regarded as a great social experiment, and its results subjected to the same searching tests as any other scientific statement.

Dr. J. S. Macdonald, F.R.S., professor of physiology in the University, made several contributions on the effect of cycling and walking on the human body. His conclusions were that the temperature steadily fell, no matter whether a person were cycling at a constantly maintained speed with no brake, or with a slight or heavy brake. To explain this he suggested that the ordinary processes of the body were in a state of suspension and the attention concentrated wholly on the exercise.

Professor J. J. R. Macleod, F.R.S., of Toronto, gave a popular lecture on insulin before a crowded audience in the Dixon Lecture Hall. He related the history of the discovery of insulin, and warned his hearers that much more had to be learnt about its nature and that there was no synthetic substitute known as yet that would be of value to a diabetic patient.

Dr. J. S. Macdonald, F.R.S., professor of physiology in the University, made several contributions on the effect of cycling and walking on the human body. His conclusions were that the temperature steadily fell, no matter whether a person were cycling at a constantly maintained speed with no brake, or with a slight or heavy brake. To explain this he suggested that the ordinary processes of the body were in a state of suspension and the attention concentrated wholly on the exercise.

To explain this he suggested that the ordinary processes of the body were in a state of suspension and the attention concentrated wholly on the exercise.

in statement of facts to give a clear working idea of the general anatomy of the human body. Part II, which comprises over half the book, contains a detailed account of the regional anatomy of the head and neck. It is clearly written and with its sectional illustrations and coloured plates should make anatomy an attractive study to the dental student.

The only criticisms we have to offer are rather of the nature of suggestions. The dental student wants to know why pain sometimes is referred across the middle line to the incisor teeth of the opposite side, and why he sometimes sees true arterial bleeding from a broken alveolar plate. We suggest greater detail in the description of the arterial and nervous supply of the jaws is desirable. The student also wants to know why a cancer of one side of the mouth infects the lymphatic glands of the opposite side, and why septic conditions of the teeth may cause enlargement of distant lymphatic glands. Again we suggest greater detail.

In general the illustrations are very good, but Fig. 8, "Atlas and Axis," is rather confusing, and Fig. 16, "Anterior Surface of Scapula," fails to convey the idea that the subscapular fossa is in reality a fossa. There are a few printer's (or reader's) errors, such as "public arch" for pubic arch, and "known as the quadrate and the lobes" (of the liver).

We recommend the book to the notice of all engaged in teaching the dental student.

### SCIENCE AND CIVILIZATION.

THE essays by various authorities arranged and edited by Mr. F. S. MARVIN under the title *Science and Civilization* for the sixth volume of the Unity Series are based on lectures given at the sixth Unity History School held at Woodbrooke near Birmingham in August, 1922. Whereas in the previous volumes the problems connected with the unity of mankind have been considered from a synthetic and general point of view, this volume is devoted to analytical discussion of the scientific factors that have bound humanity together in historical times. The editor acknowledges in cordial terms the help of Dr. Charles Singer, who contributes two out of the twelve lectures. In his account of ancient medicine he expresses the opinion that the scientific idea—the conception that the world was knowable, inasmuch and in so far as it could be investigated—arose in the sixth century B.C. among the Ionic Greeks, and that Greek medicine first put this rational basis to the test. It is held, therefore, that not only scientific medicine but our clinical tradition and standard of ethics are due to the genius of the great age of Greece. The Romans, it is alleged, did not develop scientific tastes, and it is asserted that no man of Roman blood ever wrote an important medical book. In his second article on "The Dark Ages and the Dawn" Dr. Singer describes the sleep of the Middle Ages (fifth to sixteenth centuries inclusive) and the subsequent rebirth of the scientific idea in 1543 with the appearance of Vesalius's *De Fabrica* and Copernicus's *De Revolutionibus Orbium Coelestium*; justice is, however, done to Roger Bacon's influence in bringing about the dawn of modern science. Like his other numerous contributions to medical history these two articles show, besides their extensive learning, that the proper aim of this line of research is the study of ideas rather than that of biography, interesting and attractive as the latter may be.

In the next article Professor A. N. Whitehead fixes the year 1642 as the centre of that period of about a hundred years during which the first physical synthesis was framed to form the basis of science; this year saw the death of Galileo and the birth of Newton. In describing the opposition to Galileo, Professor Whitehead remarks "it is characteristic of shocked sentiment in the case of men whose learning surpasses their genius that they begin to quote Aristotle. Accordingly Aristotle was hurled at Galileo." In his account of the influence of science on the industrial revolution at the end of the eighteenth century, Mr. C. H. Desch depicts the evil effects of machinery in the early or palaeo-technical period when social good was subordinated to

private greed and natural resources, such as coal, were wasted, and contends that only now is the neo-technical age commencing.

Professor J. Arthur Thomson writes brightly on the influence of Darwinism on thought and life, explaining the changes that have taken place in the Darwinian doctrine and illustrating its influences on sociology, religion, and ordinary human life. Two subsequent articles expand the last two subjects; in an eloquent lecture on science and religion Mr. Julian Huxley, while insisting on the limitations, maintains that the scientific manner of thinking can lay the foundation for something constructive in religion; a rigid dogma is impossible and at present science cannot discuss immortality. The editor, Mr. F. S. Marvin, in a summary of the volume entitled "Science and Human Affairs," pays special attention to sociology, balances the influence of science with that of modern philosophy, especially that of Bergson, and incidentally describes the League of Nations as the natural outcome of the unifying process which has gone on more or less rapidly for the last hundred years. In his article on the relations of science and health, Dr. F. G. Crookshank complains of the modern "scholastic" physician for dealing with "hypostatized diseases" rather than with "what happens," for considering individual cases to the neglect of the causal conditions of epidemics. Like the other articles in this stimulating volume this provides much subject for thought and cannot fail to interest the reader.

### NOTES ON BOOKS.

IN a small book of fifty-six pages Dr. R. A. BENNETT gives a useful account of *Hodgkin's Disease*,<sup>9</sup> evidently based on much reading and careful consideration of fifteen cases under his own care. He inclines to the view that in lymphadenoma the patient's lymphoid tissues are specially liable to general attack by tubercle bacilli which have been robbed of their acid-fast and more aggressive properties by the action of lymphocytes in the lymphatic glands. The action of x-rays is discussed, but no reference to radium is made. As a symptomatic remedy for fever the author has for years recommended half a drachm of pure creosote rubbed slowly into the skin of the axilla and has found this most efficacious in producing mild and continued sweating and fall of temperature; this method was employed by an old chemist who practised farriery in Cleveland many years ago, and occasionally tried his hand on human beings as well.

Since the last edition of Mr. LUSHINGTON's book on the *Law of Affiliation and Bastardy* some seven years ago the powers formerly assigned to the Local Government Board have been made over to the Ministry of Health and case law on the subject has been enriched. Consequently a fourth edition<sup>10</sup> has now been published, its author being Mr. W. B. PURCHASE, a member of the medical profession as well as a barrister-at-law. His treatment of the subject is on all fours with the scheme of most legal handbooks. All the statutes bearing on the question are cited, and it is shown to what extent their various enactments cement, or modify, or repeal one another, and how their clauses and terms have been interpreted in various courts. Mr. Purchase's exposition of the case law is very clear, and it has been brought up to a date as recent as the beginning of the current year. Though written primarily for barristers and solicitors, there are times when a reference to the chapters on legal views on the subject of gestation and of legitimacy would be found useful by medical men.

The address on the electrical structure of matter, a detailed report of which was published in our issue of September 15th (p. 474), delivered by Sir Ernest Rutherford as president of the British Association this year, together with the addresses of the presidents of the sections, have been published for the Association by Mr. John Murray in a paper-covered volume, entitled *The Advancement of Science*.<sup>11</sup> It contains 286 pages, and is illustrated by a few drawings and charts. The addresses this year may be taken as together forming a survey of the present position of most departments of science; the volume can be read with interest and is well worthy of preservation.

## CANCER RESEARCH.

In the proceedings of the Section of Surgery at the Annual Meeting, printed in this issue, in Sir George Newman's report for 1922, as noted last week, and in the *Rapport préliminaire* just issued by the Office International d'Hygiène Publique,<sup>1</sup> are suggestions for research work which, we think, deserve both support and encouragement.

We intend no disrespect to the many distinguished epidemiologists, statisticians, and clinicians who have contributed to the large literature of cancer when we say that their results have not been impressive. They have perhaps failed to be impressive because too often the field attempted to be covered has been so vast that the objects contained in it have not been distinct; all that has been created has been a general impression either vaguely alarming or vaguely reassuring.

In the documents to which we have referred above it is urged that investigations should be more specific. Mr. Herbert Paterson asks for "convincing evidence that the proportion of ultimate successes" after operations for cancer "is greater than was the case twenty years ago," and speaks of a "growing feeling of disappointment and dissatisfaction with regard to the treatment of cancer." Upon one point—the treatment of laryngeal cancer—Sir StClair Thomson was able to furnish very encouraging evidence, but there is no doubt that the assessment of results of treatment as a whole does require critical attention and a standardization of the material.

The Departmental Committee of the Ministry of Health and the commission appointed jointly by the Office International and the Health Section of the League of Nations have still more precisely localized their point of attack. In the first place, it was pointed out in an earlier memorandum presented to the Office International by the British delegate, Sir George Buchanan, that the rates of mortality from cancer of the breast and uterus in England and Wales, Holland, and Italy were very different, being much higher in England and Wales than in the other countries, although the rates of mortality from all forms of cancer in England and Wales and Holland were not dissimilar. It was suggested that the statistical experts of the various countries should first determine whether these striking differences were explicable on purely statistical grounds—that is, as consequences of varying accuracy of certification. The suggestion to inquire in this direction was accepted, and in a further report, presented during the following session of the Office, which contains valuable memoranda from the statistical departments of ten countries, it is concluded that the differences found to exist are not mere paper differences, but proofs that the fatal incidence of the particular forms of cancer under notice is indeed unequal in the three countries.

This conclusion having been reached, there was a strong case in favour of attempting to account for the differences, and, as briefly indicated in Sir George Newman's report, a further inquiry has been set on foot.

The line this inquiry, which is controlled by a strong committee representative of the three nations concerned under the chairmanship of Sir George Buchanan, will take is, we understand, the following. The various hypotheses adequate to explain the facts will be tested in order of a *a priori* likelihood. Thus, the explanation having the greatest such probability in its favour is that in the countries experiencing a relatively

low incidence of fatal cancer of the breast and uterus either the proportion of attacked persons who submit themselves to operative treatment is larger, or the average previous duration of the disease in those seeking treatment is shorter, or both factors operate to the advantage of the less afflicted nations. The testing of this hypothesis will involve a careful comparison of the hospital experiences of the three countries—a statistico-clinical research involving the close co-operation of practitioners and vital statisticians. If it be found that data thus accumulated do not establish any sensible difference between the nations in the matter either of frequency or date of treatment, the comparative frequency of possible etiological factors will fall to be considered. Data for this inquiry will naturally be collected simultaneously with those of a more restricted scope. In this way, advancing slowly, step by step, testing each conclusion reached in the light of clinical and statistical knowledge, it may fairly be expected that definite additions to knowledge will be secured.

We have no doubt at all that this is the right plan of campaign for a clinico-statistical research—namely, a very careful delimitation of its objectives and the fullest possible co-ordination of different arms of the service. This is an admirable choice of subject for international research work—it avoids, on the one hand, the delegation to an international body of studies which can be as well carried out in particular universities or national departments or even by private individuals, and, on the other, the common vice of proposing for solution some immense problem which is beyond the reach of any existing means of investigation.

## LIVE ANATOMY.

No movement in modern British medicine is more welcome than that led by some of our younger anatomists who have caught the spirit of Sir Charles Bell and returned to the teaching of living, functional anatomy. A member of this group is Dr. S. E. Whitnall, who until he was called from Oxford to succeed Sir Auckland Geddes in the chair of anatomy at McGill University was known to his British colleagues for his researches into the anatomy of the eye and orbit, and more especially for his gift of covering a great seriousness of purpose by a happy sense of wit and humour. At Oxford he became imbued with the learned humanity which animated one of his teachers—Sir William Osler—and this spirit he has carried back to Sir William's Dominion and allowed it to bubble freely over into a little book which he has entitled *The Study of Anatomy*, intending it for his own students.<sup>1</sup> It deserves a much wider circle; we hope it may spread into every medical school where the English tongue is spoken, for it contains happily expressed precepts which young and old will find helpful and stimulating. The essential lesson Professor Whitnall wishes to press home to medical students is that, on entering the dissecting room, they must keep their imagination as sharp and as lively as their scalpels, and on entering the hospital wards they must keep the same faculty equally alert when they palpate, percuss, or auscultate, if they are to reach the source of illness. The beginner, he says, who looks on the skin of his "part" as merely something which has to be removed is wasting his opportunities unless he also remembers that it is a living sentient organ endowed with functions which are essential to health and life. The student who has displayed all the structures of his part

<sup>1</sup> *The Study of Anatomy*. Written for second year medical students. By S. E. Whitnall, M.A., M.D.Oxon. Montreal: Renouf Publishing Company. 1923. (Double Cr. 8vo, pp. 46. 2s. 6d.)

The closely related *Demodex folliculorum* lives in animal glands and amongst animal cells which may lose their power of resistance owing to chronic irritation or other cause. Is it not probable that the demodex may cause these cells to revert to a more primitive—an embryonic type?

That these primitive cells, growing and multiplying out of their proper time and place, may run amok amongst the surrounding tissues and so cause cancer?

This suggestion I offer for what it is worth. It opens an avenue for investigation which, as far as I know, has not yet been explored.—I am, etc.,

J. MCNAMARA, M.D.

London, W., Sept. 2nd.

# MEDICAL EDUCATION IN INDIA.

SIR,—A question of vital importance to the advancement of medical education in India seems to have been discussed at a meeting of the Bombay University Senate. A number of students have been refused admission by the Dean of the Grant Medical College to the Intermediate M.B., B.S. class, the reason of the refusal being lack of clinical accommodation, especially in the midwifery wards. The latter difficulty seems to have been created by the British Medical Council's rule, lately introduced in India, that every student must attend twenty labour cases during his period of training for a medical degree.

In my opinion this is very hard in a country where the generalty of women do not prefer to see male medical attendants and where the demand for duly qualified medical men is increasing every year. In my time we had to conduct six cases per student and were none the worse for that. I remember how some of us were anxious to have some more cases than their due quota, but were not allowed that indulgence.

If at all the instance of the General Medical Council is a greater number of confinement cases has to be done now by every student, and if there be not sufficient accommodation in the central teaching hospital, I am sure the Dean of the Grant Medical College can increase the available accommodation by seeking co-operation with other institutions. Besides the Cama Hospital for Women and the Pervere public hospitals which could easily make teaching accommodation for a number of students every year according to the number of their beds. Allowing more students to witness the same case at the same time under suitable circumstances should also ease the situation in a perceptible manner.

In England the students can go out to attend at the patients' houses in order to finish their twenty cases. Fostering the sentiment being so different in India from that in England, it will be a matter of many more years, if not decades, before Indian students can enjoy the same facilities in this direction as their British fellow students. It should be within the bounds of justice and fair play if the General Medical Council would consider the difficulties of Indian students and without starting medical education in India, at least till a suitable increase in the existing accommodation at the teaching hospitals is made as intended.—I am, etc.,

A. D. JINNA.

London, S.E., Sept. 1st.

\* Our information with regard to the position in Bombay is not quite recent, but we believe some of the statements made by our correspondent to be out of date. We hope to recur to the matter shortly, and meanwhile would invite readers to suspend judgement.

# SPIRITUAL HEALING.

SIR,—In the correspondence on this subject in the JOURNAL and elsewhere, it seems to be taken for granted that organic diseases have been healed by the methods used—the hypothesis of spiritual healing is dismissed—

that should the claims made be substantiated—namely, that should the claims made be taken for granted in the correspondence on this subject in the JOURNAL and elsewhere, it seems to be taken for granted that organic diseases have been healed by the methods used—the hypothesis of spiritual healing is dismissed—

able, so that a scientific explanation becomes impossible. Which supporting your correspondence in their desire for the establishment of an exact diagnosis in the cases, I suggest that should they prove to be instances of organic disease an explanation will be possible inside the domain of science. It may be necessary to enlarge certain biological concepts just as on many earlier occasions new facts have entailed readjustments in biology and in the physical sciences.

As to what that new hypothesis shall be—let us first get the facts as accurately as possible. A scientific understanding will obviously be no more in conflict with religion if the cases prove to be organic than if they prove to be non-organic in origin.—I am, etc.,

London, N.W., Sept. 2nd.

M. D. FOSTER.

# HIPPOCRATES.

SIR,—Mr. W. H. Jones's interpretation of the *Corpus of Hippocrates*, as quoted in your issue of September 15th, 1923 (pp. 481-482), may be admirable, but his scholarship seems scarcely in keeping with the high standard that has hitherto characterized the Jacob classics. Is there any doubt as to the correctness of Professor Stricker's distinction between the meanings of *moros* and *allos*?—a distinction rigidly maintained throughout classical Greek.

Does primarily mean "work, hard work, toil, labour," mostly "toil of war," but also "bodily exertion, hard exercise." Its secondary meaning is "the consequence of such toil, distress, trouble, suffering, pain." *Oikos* is always used to express "pain of body" and "pain of anguish of mind," and, further, is exclusively employed for "the pains of childbirth."

I have not read the passages in which the two words occur, and I admit that Mr. Jones's words are, "they seem practically synonymous," but, as Professor Stricker rightly points out, Hippocrates used words whose meanings were recognized and accepted throughout Hellas, and gives to every word its particular primary connotation.—I am, etc.,

Elmer, Surrey, Sept. 2nd.

Herbert E. Gray.

# PAY OF THE R.A.M.C.

SIR,—The pay of married officers in the Army Medical Service is inadequate. The expenses in the army to a married man are totally different to civil life. As it is impossible to get unfurnished houses, he will have to live in a furnished one, which will mean a rent of £150 per annum. He will get on an average a change of station every eighteen months, and though the Government pay is given, necessitating taking another house with probably several months of the lease of the vacated one still to run, and unable to sublet. A short time ago I was paying 4 guineas and 3 guineas a week for two months. The specialist's pay of 5s. per diem is a farce, under the new regulations he will actually get 2s. 1d. per diem, and the 2s. 6d. per diem is reduced to 5d., which seems a poor reward for special knowledge in a particular subject.

Promotion is very slow, and for the majority of majors almost hopeless. There is no rise of pay after fifteen years until twenty-six years. The pension, which before the war was £265 per annum after twenty years' service, is now about £240, which hardly represents the increased cost of living.

Added to all this the R.A.M.C. is rapidly becoming a foreign service; the home tour is becoming shorter and shorter, bringing with it the usual problems of family separation, education of children, etc., and little or no compensation in the way of increased pay. I enclose my card.—I am, etc.,

September 2nd.

Major R.A.M.C.

problems affecting India as a whole, to co-ordinate the work of provinces, and to be the channel of communication between India and other parts of the world. Dr. Choksy's articles have thus the merit of propounding a constructive policy, and it is a policy with which hygienists generally are likely to agree. It has also the merit of being evolved and strenuously advocated by one whose medical education has been indigenous, and who is intimately acquainted with the political and medical history of his country, its possibilities and aspirations, and the social and sanitary conditions which form such an obstacle to comprehensive and effective measures of public health.

#### THE MEDICAL HISTORY OF THE WAR.

THE volume on pathology<sup>1</sup> in the official Medical History of the Great War has been issued, and will probably prove to be not the least interesting of the series. There still remain to be issued three volumes containing accounts of the administration, organization, and employment of the medical services in all theatres of war; but the new volume completes the account of what may be called the scientific aspects of the work of the medical services. We congratulate Major-General Sir W. G. Macpherson, K.C.M.G., editor-in-chief of the series, on the completion of a laborious and anxious duty. The first volume, issued at the end of 1921, contained a general review of the task set to the medical services and the manner in which it was met; this was followed by two volumes on diseases of the war and two on the surgery of the war. Recently two volumes have been issued on the hygiene of the war; they were reviewed in our last issue. The series is issued by the Stationery Office, and the volumes can be obtained through any bookseller. They are well printed, reasonably well bound, are of a form convenient for holding in the hand, and are fairly well illustrated. In some instances the names of those who have assisted Sir William Macpherson in editing a volume have been given, and in all a list of contributors is inserted. Each volume is divided into chapters in the ordinary way, and here we cannot help feeling that the interest of the volumes and the ease with which they may be consulted will be diminished by the fact that the names of the authors are not prefixed to the chapters. In some instances a single chapter has been composed or revised by several writers; in others it appears that the whole of a chapter is from one hand. For example, a note issued by the War Office states that Sir W. B. Leishman has contributed to the volume on pathology the first chapter, which is on the organization of the pathological services, and that it is founded on his own experience as adviser on pathology on the Western Front throughout the war. The same note gives also the names of several other authors, and by a study of the list of contributors we can ascertain that Sir Almroth Wright is the author of a chapter on the physiology of wounds, and that Professor Clifford Dobell and Colonel W. Harvey, C.M.G., formerly Deputy Director of Pathology at the War Office, are jointly responsible for the chapter on the pathology of dysentery. But in other volumes, and even in this, it has not always been easy to ascertain by comparing the list of contributors with the headings of chapters what writer was responsible for what chapter; this has been a pitfall for reviewers, as we have found by some unfortunate experiences; the most recent was the inadvertent attribution of the whole of the chapter on skin diseases in the second volume of *Diseases of the War* to Dr. Henry MacCormac. Reference to the list of contributors shows that Dr. A. M. H. Gray, who, like Dr. MacCormac, was a

consulting dermatologist with the British forces in France, joined with him in writing the chapter, and that Major J. A. Manifold, assistant professor of pathology R.A.M. College, was responsible for the greater part of the section on tropical skin diseases, and Major T. J. Mitchell, R.A.M.C., for the paragraphs on Oriental sore. Having delivered ourselves of this grumble we hasten to add that the series is a most valuable contribution, not only to military medicine, but to medicine in its widest sense. It is a mine of information into which future inquirers and writers will often delve.

#### TRAUMATIC OBLIVION.

A short time ago the rider of a motor cycle who had knocked down and killed a man affirmed that he could not recollect anything of the accident, and evidence was given by a medical witness in support of the story. After a blow on the head severe enough to produce unconsciousness it is very frequent—it may almost be said to be the rule—for the injured person to find that he is not only oblivious of what happened during the time that he was unconscious, but also that he has no memory whatever of what happened for some time previous to the blow on the head. Moreover, afterwards he may perform ordered acts and forget all about them. There may be a complete lapse of memory between a short time before the accident and some hours, or even days, afterwards. The memory of these pre-traumatic experiences sometimes returns in a fragmentary manner, but more often it is permanently lost. The case we have mentioned has led a correspondent (Mr. Hubert Visick) to send us the story of his own experience when a student at Guy's. He had gone from lodgings at Streatham on a Saturday morning to skate near Guildford; while playing hockey he tripped and fell, cutting his eyebrow. He was picked up, but refused all assistance; skated to the side of the pond, removed his skates, and walked to his uncle's house, a distance of a mile. While his head was being bathed he suddenly became conscious of his surroundings, and was much astonished to find himself where he was, having no recollection of leaving his lodgings at Streatham. He has never recovered the memory of the events which happened between going to bed on Friday night and Saturday afternoon. During the interval after the fall his demeanour did not suggest anything unusual to his friends, who said that he talked rationally on the way to the house. In an article published in our columns eight years ago (September 18th, 1915, p. 445), which we may now say was written by the late Dr. Charles Mercier, he suggested an explanation of pre-traumatic oblivion. It is generally assumed that every experience of which we are conscious produces a modification in the finer elements of structure in the cerebrum; that is to say, that the conscious memory of an experience answers to a structural modification of some kind. It may be assumed also that the brain possesses the physical quality of elasticity; that is to say, that its structural elements not only oppose resistance to disturbance, but, when disturbed, tend in certain circumstances to resume their original positions. When under the action of sense impressions, or otherwise, the structural elements of the brain are shifted into new positions a considerable proportion—it may be the whole or almost the whole of them—resume their original positions after longer or shorter intervals. This is only to say that we never remember all we see, or hear, or otherwise experience, and that of much we experience we retain only a remnant, and that the process of forgetting begins as soon as the experience is over, and thereafter continues at a varying rate. Sleep has a twofold effect on memories—some it fixes, some it wipes out—and this fact has some bearing on the subject under consideration. Imagine a brain, in the course of experiencing new impressions and of registering

<sup>1</sup> *History of the Great War, Based on Official Documents: Medical Services, Pathology.* Edited by Major-General Sir W. G. Macpherson, K.C.M.G., C.B., LL.D., Major-General Sir W. B. Leishman, K.C.M.G., C.B., F.R.S., LL.D., and Colonel S. L. Cummins, C.B., C.M.G., LL.D. London: His Majesty's Stationery Office, 1923. (Demy 8vo, pp. 600; illustrated, £1 1s. net, post free £1 1s. 9d.)

with the societies on a certain date, if satisfactory assurances were not received; an agreement, however, was eventually reached.

done when the cervix is open, and thus passed into the uterus. They point out, again, that no packing should pass through the cervix, as the raw area in the lower uterine segment is easily infected. In some other schools, however, plugging is very rarely practised in cases of placenta praevia, because usually the cervix, when the condition is diagnosed, will admit two fingers, and then it is definitely contra-indicated, as version can be performed. The number of abdominal pregnancies—four, with two living children and only one maternal death—is very interesting, as this rare complication is seldom seen. With regard to operative procedures, Caesarean section was performed in twelve cases only, showing that the operation is not undertaken without due consideration. In cases operated on for the first time, the lower uterine segment operation was always employed. There were no deaths from Caesarean section. Pubiotomy was performed on eight occasions, with one maternal and four infantile deaths. This latter operation is undertaken, however, at the Rotunda Hospital somewhat more frequently than is usual elsewhere, and is performed instead of craniotomy for contracted pelvis if the child is thought to be alive. After the pubic bone has been divided labour is allowed to progress naturally, forceps are not applied, and the child delivered at the time of the operation; thus in two cases labour went on for eleven to fourteen hours after division of the bone, the infant succumbing in both cases. Induction of premature labour for contracted pelvis is favoured in suitable cases, a 30-inch No. 24 stomach tube (soft rubber) being employed instead of bougies, as the tube can be sterilized more thoroughly. Sea-tangle tents are used for induction before the twenty-eighth week. Dr. Fitzgibbon and his colleagues advise that several tents should be used instead of one large tent, and that they should all be introduced through the internal os. In the treatment of hydatid moles, of which six instances occurred during the year, curettage with a flushing curette is advised seven days after removal of the mole, whether it came away spontaneously or not, as there is always a large amount of debris in the uterus. The operation can, it is stated, usually be performed easily without an anaesthetic. Besides the maternity cases, 433 gynaecological cases were treated and 325 operations performed in the hospital, the mortality being 2.2 per cent.

#### KITCHENER MEMORIAL MEDICAL SCHOOL AT KHARTUM.

The account which Dr. O. F. H. Atkey, Director of the Medical Department, Sudan, gives us at page 581 of the scheme of the Kitchener Memorial Medical School at Khartum more than justifies the appeal which is about to be made in this country for contributions to an endowment fund. The idea of the school was conceived by Lord Kitchener during his last visit to the Sudan, and it will help to complete the educational scheme he initiated when he founded the Gordon Memorial College immediately after the battle of Omdurman. In doing so he showed his faith in the people of the Sudan at a time when the country was desolated by war, famine, and disease. He knew them well and appreciated their qualities. Except in the extreme south the Sudan is inhabited by an Arab race possessing something of the intelligence and love of knowledge which through mediaeval times kept alive the torch when medicine, and science generally, throughout Europe were in eclipse. The people of the Sudan to-day have shown their approval of the project in a most practical way, by themselves subscribing over £11,000 and by other gifts. Up to date all expenditure has been met, and £20,000 has been subscribed towards the endowment fund. The appeal is now for £40,000 to complete the fund, which will be devoted to maintenance and to meet the cost of an adequate teaching staff. At present teaching is carried on by members of the Government medical service, but they have

other duties, and the plan is obviously only a makeshift. The need for a larger staff is indeed urgent, since at present it will only be possible to accept twelve students a year, but it is clearly desirable to make provision as soon as possible for a much larger number, all of whom, it may be expected, will quickly be absorbed. From a medical point of view the scheme seems to be framed on right lines. Students are to be given a sound training in modern medicine up to a certain definite standard, so that if later on they can be brought back to the school it will be possible for them to resume their training without having to unlearn anything. Eventually it is intended, when the staff can be made adequate, to extend the curriculum to five years, and it is hoped that before very long the school will take a leading part in the civilization and development of north-east and central Africa, and, working on the same lines as those followed by the medical schools of Europe and America, produce really good scientific work.

#### THE CENTENARY OF THE "LANCET."

On Sunday, October 5th, 1823, the first number of the *Lancet* appeared, and in celebration of the event a special number of the journal will be issued on October 6th, and a centenary dinner will be held in London on the evening of Thursday, November 29th, at the Hotel Victoria, Northumberland Avenue, London, W.C., at 7.30 for 8 p.m. Sir Donald MacAlister, President of the General Medical Council, will take the chair, and will be supported by the Presidents of the Royal Society, the Royal Colleges of Physicians of London, Edinburgh, and Dublin, the Royal Colleges of Surgeons of England, Scotland, and in Ireland, the Chief Medical Officer of the Ministry of Health, the President of the British Medical Association, and the Presidents of the Royal Society of Medicine and of the Medical Society of London. The Minister of Health has signified his intention of being present, and it is hoped that a gathering representative of all the interests associated with the medical profession will meet on this occasion. Those who desire to be present should communicate at their early convenience with Mr. H. D. Gillies or Dr. J. H. W. Laing (honorary secretaries) at 7, Portland Place, London, W.1. The charge for the dinner has been fixed at 15s., exclusive of wines, and if notice be given in advance endeavour will be made to arrange that friends who so desire shall sit together.

#### AN ANTIVACCINATION FALLACY.

ANTIVACCINATION fallacies are so numerous—or numberless—that one more or less does not matter, but lately special emphasis has been laid on the fact that vaccination and small-pox have been declining together for years past. Of course they have, and when small-pox reappears, as recently in many parts of the country, vaccinations also mount up. Under voluntary vaccination that will always be so. There is no teacher of vaccination like small-pox, and the "anti" advocate will always be able to point out that when small-pox abounded vaccination abounded, and vice versa. The only fallacy is that cause is substituted for effect and effect for cause—which is a mere trifle to the antivaccination intellect. It is because small-pox is absent that vaccination is at a low ebb, and when small-pox returns so will vaccination.

SIR ARCHIBALD GARROD, M.D., F.R.S., Regius Professor of Medicine in the University of Oxford, has been appointed a member of the Medical Research Council in succession to Professor F. Gowland Hopkins, F.R.S., who retires by rotation. The appointment of Sir Archibald Garrod was made by the Committee of the Privy Council for Medical Research, after consultation with the Medical Research Council and with the President of the Royal Society, by Order of Council dated September 11th, 1923.

large income for the sake of an academic life. Such men also usually find that the work of a professor as they conceive it is so exacting that it leaves no time for anything else. It must be said that this monastic view of the professoriate of medicine has never been taken anywhere else than here and in a few American schools, and it is certainly unreasonable to insist upon it everywhere. There are, at any rate, other possibilities. A comparatively young man might, for instance, be elected for a limited number of years, on the understanding that after that he might resign his chair and take a practice, or that the university might think it better not to re-elect him. There is something to be said for such a plan, for a man's invention rapidly deteriorates, while his experience and his judgement advance, and this method might be a means, if not to give him the best of both worlds, at least to give both worlds the best of him. But it has also disadvantages which are equally obvious. Or, again, it might be preferred that the professor should be the embodiment of judgement and experience, and that the more imaginative qualities which are certainly needed should be supplied by an assistant, who should be placed above the necessity of practice.

Opinions will differ, too, as to the part which the professor should play in the school organization. At one school he may be given the charge of organizing the whole of the teaching in the final subjects, while in another he may be merely a colleague working alongside the other members of the staff, and on the same terms with them.

For some time to come circumstances will differ, and the plans adopted will differ accordingly. But, so far as the first of these points is concerned, it seems not unlikely that the best candidates for the chairs will themselves prefer an academic life and ask to be relieved from practice, while if they do so the universities will probably find means to render this possible.

The remainder of the staff is, in London itself, treated with even more variation. At one school the first assistant may have part of the day to himself, while the juniors are fully occupied; at another the reverse may happen, or the same school may vary its conditions at different times to suit the persons concerned. The more variation the better. The paid assistants are not, however, the only persons on the unit staff, for these units are centres to which are drawn not a few graduates from other countries, especially from Canada and the United States, who wish to come to Europe and to work under European teachers. In at least one instance a London professor has taken duty for a colleague in America, and the latter in his turn has acted temporarily for the professor here.

We may hope that the poverty of the universities, which sadly hinders the introduction of expensive changes, may gradually be relieved, though we can hardly expect to obtain the immenso endowments which universities, and especially medical schools, have received of late years in America. In that country gifts to education have taken the place of those gifts to religion by which our forefathers sought to perpetuate their names in this world and to mitigate their sufferings in the next, and the restricted insight which leads men to prefer material benefits to others has turned such gifts almost entirely to the scientific, and chiefly to the medical departments. The same tendency is visible here, but the donors are less wealthy and are therefore ransomed at a smaller cost. In America, too, there are few other objects on which a man may spend largely; in the old world there are many; and since our Governments have not hitherto accounted public benefactions of this kind worthy of honour, public giving has turned rather to those channels which conduce to the rewards that good men naturally desire.

### III.

It remains to consider the effect of recent changes upon the student. It was allowed, even by those who criticized the system then existing among us, that the practical instruction of the British and Scottish schools was probably the best in the world. Nowhere else was the feeling of responsibility, which is the best of all incentives to learning, so early developed as with us, and nowhere were general

practitioners so competent. Our methods had been imported into American schools, and American physicians were unanimous in approving them. Criticism turned rather upon the future outlook of the men we trained. It was alleged, but on *a priori* grounds and without any attempt at comparison with other countries, that though they left the schools excellently equipped for practice they were not so trained in what may be called by contrast the theory of medicine as to lead them to pursue independent research in their daily work, or to assimilate for practical use the gradual advance of physiological and pathological discovery. It must be repeated that this was almost entirely founded upon what the critics thought our training would produce, rather than upon any actual observation of the conduct of the living, wriggling general practitioner himself in this and in other lands; and even so, no one wished that the practical excellence which was admitted to exist should be impaired, but it was desired to add to it a deeper study and a profounder view. Everyone acknowledged that it was of the first importance to the public that a man should know the clinical significance of what he saw or felt or heard in the patient's body, but the critics added that he should be trained continually to question the meaning of these phenomena, to refer them to wider physical laws, or to seek explanations in the most recent results of physiology and pathology.

The recent advances in these sciences have led to an astonishing increase of those methods of clinical observation which depend upon the test tube and the microscope. The student has many more ways of observing his patient than he had aforetime, and a complete account of any single case of disease is much longer and much more complicated than it used to be. The employment of new methods raises many fresh questions in his mind. He asks himself why this element in the blood is decreased or augmented, or why this constituent in the urine is absent or enormously in excess. His horizon is extended, and with the addition of each fresh phenomenon to the sum of his observations a fresh object is afforded to curiosity. All such fresh work is ill understood at first, but behind the outer fringe of new observations law gradually advances, consolidating—as the soldiers say—the territory won, classifying, reducing to regularity—or, as we call it, explaining the phenomena—and adding width and depth to the science of medicine.

It is, of course, true that these laboratory methods are on the one hand so laborious that few have time to continue them in after-life, and also need such constant exercise that to use them only occasionally as private practice offers is probably more dangerous than profitable. Yet a man who has used them and understood them will better realize what they mean and what they can effect. He will be able to some extent to form his own judgement on laboratory reports, and will not put a penny in the slot and expect an answer to all his difficulties.

Yet it must be acknowledged that there is a little to be said on the other side. The new labours entailed upon students undoubtedly diminish the time they can spare for the practice of the old methods. The time spent with the microscope is not spent with the stethoscope, and that given to the laboratory is so much taken away from the training of the eyes to see, the ears to hear, and the hands to feel the body itself. This is in a measure compensated by the greater labour of the teachers. The student is an instance of intensive cultivation. He is taken over his work by one teacher after another, and the effort is made by constant pressure to squeeze into him in a short time that which he used to absorb more slowly by himself. But there is no denying that something is lost by these methods. The student thinks less for himself.

Nor can it be denied that the multiplicity of the phenomena diminishes the consideration which can be paid to each. The horizon is vastly extended, but there is less opportunity to dwell upon any of its details. There is even some fear that the change may lead to the direct opposite of what was intended, and may, while greatly increasing the student's information, tend to a more superficial rather than to a profounder habit of thought.

This has led some to question whether all that can be

2 | that historians have suggested that

## THE STATE OF THE PUBLIC HEALTH.

SIR GEORGE NEWMAN'S REPORT FOR 1922.

(Concluded from p. 538.)

## LOCAL SANITATION.

AN account is given on established lines of work under the Ministry of Health relating to water supply, sewage disposal, rivers pollution, scavenging, and general environmental hygiene. Smoke abatement receives particular attention, and Dr. Niven's health report on Manchester is referred to. The Committee on Smoke and Noxious Vapours Abatement (1921) suggested the compulsory use of mechanical contrivances for avoidance of smoke, the establishment of combined "smoke authorities," and the appointment of expert smoke inspectors under the Ministry.

As to scavenging, attention has been given to defective methods of disposal of London refuse in the adjoining counties. A conference was held, and a joint consultative committee issued a statement as to precautions which should be taken concerning refuse tips—shallow layers of refuse promptly covered with earth—the prevention of fire, and the covering of railway trucks and barges during transit of refuse. Methods of disposal by salvage and pulverization plants are being kept under observation.

It is pointed out that offensive trades should be controlled even if effluvia or emanations cannot be proved injurious to health.

## Isolation Hospitals.

Isolation and small-pox hospitals have been the subject of inquiries and inspections. Several so-called small-pox hospitals are such merely in name.

"Old cottages, temporary structures, without proper accommodation for the nursing staff, insufficiently ventilated, deficient in water supply, lacking facilities for bathing and washing, with inadequate drainage and means of sewage disposal, are considered by certain sanitary authorities, in the absence of small-pox, sufficient provision for the reception of patients suffering from small-pox. When small-pox occurs in these districts, the hospital accommodation, such as it is, is inadequate to receive even the first few patients and gross overcrowding results.

"In a recent visit to one of these hospitals, a medical officer of the Ministry found three patients suffering from small-pox in a so-called ward measuring 12 ft. by 9 ft. by 7 ft., the cubic space per person being less than that usually provided in a common lodging-house, and the floor space being one-quarter of that recommended as necessary by the Ministry."

"The Ministry has no legal authority to compel a sanitary authority to provide an isolation or a small-pox hospital nor to regulate the use of such hospitals when provided."

## VENEREAL DISEASE.

Good work continues to be done under the venereal disease scheme, notwithstanding that need for economy has led to the closure of a few smaller centres. Beds for in-patients are available in connexion with most of the centres. Sixteen hostels have accommodation for 271 women and girls, and treated 584 cases, their work being valuable in preventing ophthalmia neonatorum and infantile syphilis. In 1922 effort under the scheme was directed mainly to improving efficiency by increased thoroughness in treatment, by adding to the facilities for the treatment of gonorrhoea, by more convenient arrangements for patients, and by improving equipment where required. Sufferers from syphilis are more readily convinced of the value of due attention than are those with gonorrhoea. The report states that "Unfortunately, in a number of centres the treatment of gonorrhoea still falls short of the best modern practice, and in these cases it is not surprising that the official clinics fail to attract anything like a due proportion of cases of gonorrhoea." In women efficient treatment of gonorrhoea is a most exacting task. Gonococcal vaccines are being found of undoubted service in appropriate cases, both of women and men. The importance of tracing contacts is insisted on, for a syphilitic child means a syphilitic mother, and the prospect of more syphilitic children.

The number of fresh infections of syphilis has certainly fallen, and the impression strengthens that gonorrhoea is also on the decline. The number of cases dealt with for the same time in 1922 was: syphilis 25,762, against 32,733 in

1921, and gonorrhoea 29,477, against 32,433. Cases other than venereal number 16,988. The total number of attendances was 1,560,568.

## FOOD IN RELATION TO HEALTH.

## Milk.

Control and grading of milk—"certified," "Grade A (tuberculin tested)," "Grade A" not so tested, and "Pasteurized milk"—are the main features of present-day supply. Of 2,400 animals which passed the tuberculin tests 1,500 were on "certified" farms and 900 on "Grade A" farms; the herds were daily producing 2,250 gallons of "certified" and 1,350 gallons of "Grade A" milk. Bacteriological sampling yields improving results; in 1920, 71.2 per cent. of samples were satisfactory; in 1921, 75.4; and in 1922, 81.7; the numbers on which these percentages were based rose from 60 in 1920 to 142 in 1921 and 338 in 1922. But the average consumption per head of milk in Great Britain is less than a third of the United States average, though the need of the children for milk is equally great in both. It is hoped that the improved keeping qualities of milk, and public knowledge of its better quality, will promote its use. The essentials are clean and healthy herds, clean milking, effective and immediate cooling, prompt bottling, and clean and rapid transit.

## Meat Inspection.

The code of instructions for inspectors prepared by the Departmental Committee on Meat Inspection (1921) was issued by the Ministry after emendation. The report gives an account of action taken and under consideration for preventing importation of unsound meat from abroad—tuberculous pork, pig's heads with submaxillary lymphatics removed, and certified "inedible" grease from the United States manufactured abroad into "refined lard" for sale in this country.

## Food and Drugs.

The administration of the Sale of Food and Drugs Acts is still under the influence of post-war economy. Of over 60,000 samples of milk, 8.6 per cent. were found adulterated; of over 11,000 samples of butter 2.4 per cent.; of 3,700 margarine 0.7 per cent.; of 1,878 cream and preserved cream 23.7 per cent.; of vinegar 6.2 per cent.; coffee 1.5 per cent.; spirits 14.6 per cent.; drugs 6.7 per cent.; and other articles 3.6 per cent. The number of drug samples was 5,863, and the total samples, including all the above, 113,800. The electrolytic method of estimating arsenic has been improved greatly, and is of value for finding the metal in food, the source usually being arsenical sulphuric acid, or ingredients dried in contact with fumes from arsenical fuel.

## Shellfish.

Various investigations of shellfish were made during the year, but the report protests against the insufficiency of the information often sent where enteric fever is attributed to consumption of shellfish. The "Weymouth (Shellfish) Regulations, 1922" have been applied to forbid the relaying in Portland Harbour of oysters for human food, the harbour being polluted by crude sewage.

## Food Poisoning.

An account is given of various inquiries into chemical poisoning, where lead, copper, or zinc, or, in one case, potassium nitrite, was concerned. Bacterial poisoning occurred on a considerable number of occasions, the articles of food brought under suspicion being very numerous, including meat, fish, and fruits. In many cases an organism of the Salmonella group was isolated. An outbreak of dysentery at Lynton was traced, through milk supply, to a farm hand who had served in the East and was found to be an active carrier.

## INSURANCE MEDICAL SERVICE.

With most of the facts mentioned in this section of the report readers are already acquainted, and the least familiar matter, the rheumatism inquiry, is referred to elsewhere in this notice, but we may quote the following paragraphs:

"The number of insured persons entitled to medical benefit in 1922 was (approximately) in England 12,690,000, and in Wales

devotion and thus to narrow their intellectual outlook and their chest development; to them, therefore, it is not so necessary to insist on the obvious need for industry, "what Sir William Osler in his charming *Learnings* called "the Master-word in Medicine," as to remind them that the best realizations of the ideal of the *mens sana in corpore sano*. It has not uncommonly been urged in introductory addresses such as that heard alone seldom leads to a breakdown and that hard work or some extraneous factor is the real cause; this is a rather overstated, though no doubt admirably meant, exhortation, and is perhaps more applicable to those whose life's work is free from the menace of the examination body than to the student, especially women, whose mental vision is too often focused anxiously in that direction. It may be partially true when hard work can be secured from worry, but even then the interference with physical health must be taken into consideration. Much, therefore, turns on how the work is done, wisely or otherwise, and on the physical and mental make-up, so to speak, of the individual; women students especially should remember that there are occasions when the willing spirit should be mindful of the weakness of the flesh, and that as a class they are more liable to mental breakdown from overwork.

There are disadvantages in reading too much; as epigrammatically put by Sir James Kingston Fowler, "if you want to be original you must not read too much." This may sound like an invitation and encouragement to idleness in the face of the enormous amount that medical students have now to assimilate, and reality to be a more first sight a paradoxical statement, excessive reading may be a pecuniary worry of laziness in so far as it is a means of escape from that much avoided process of thinking for oneself; how much easier it is to look up at once in a book first in one's mind. The real moral, therefore, is to read wisely and to spend time in thinking over and applying to actual cases what has been read, instead of aiming at a facile familiarity with the windy doctrines of so many textbooks. The danger of over-reading may at first sight seem chimerical, but it largely consists in using up time which would be better spent in thoughtful and practical observation. At the present time radiograms and other laboratory tests so greatly assist in the study of the patient in a serious danger of being neglected. The experience gained from one or two good clinical cases is worth half a dozen textbook descriptions and is likely to be remembered much longer. The habit of accurate observation is not easily acquired; reading may fill you with look for, but it cannot take the place of observation which properly brings wisdom—a far more valuable property than mere learning. The bookish student may repeat like a parrot the words of the wise without understanding them and break down worry in practical work. There are several methods of reading, and by far the best is that which is accompanied by thought and by an argument on the mind at the time and not providing a concise précis of the subject for future reference. It is a mistake to read too long at a time at one subject, for this leads to mental fatigue, to which girls are more susceptible than their brothers.

In the opinion of experienced teachers, such as Professor W. D. Halliburton, while the average female student is on the whole superior to the average male student, possibly because the women who take up science are usually keener so able as the best men students. This estimate indeed is on the same lines as the generally accepted view that true genius is even rarer in women than in men. Nor whether this is due to inherent sex peculiarities or is the result of long-continued dominance of the male sex or to both these factors is an academic though interesting question.

It has been stated that each individual contains the potential elements of both sexes, one being of course dominant.

spontaneous with the influence of the hormones from the endocrine glands, especially the gonads. According to Otto Weininger and W. L. George "there are no men, there are no women, but only sexual majorities." Although this view may not now be accepted and the endocrine glands are now considered to influence emotional rather than intellectual activities, there are most remarkable individual differences among members of the same sex, and everyone has known feminine men and virile women. As all kinds make a world, provision must be made for all, and it is among the masculine minded women that variability tending to the production of genius or of special ability may be anticipated. Perhaps too much stress has been laid on the small number of women doctors who have made epoch-making advances and on the view (correct as it may be) that as a rule women students are less original in mind, less inclined to initiate new lines of thought, and are more successful as conscientious followers than as independent leaders in research. There have been exceptions in the past to any such rule, there are more in the present, and in the future there can be little doubt that women workers will take an increasingly larger part in research, whether independently or under the inspiration of a great teacher. The establishment at the Royal Free Hospital of a whole-time Professor (Dr. Louise McIlroy) of Obstetrics and Gynaecology with a clinical unit is a notable step in advance and offers opportunity for realization of this belief.

But after all, success in our profession is not measured solely by ability for research and the discovery of truth, but after all, success in our profession is not measured by the gift of prophecy (prognosis), and understanding all systems (diagnosis), and all knowledge; and though I have all faith, so that I could remove mountains (confidence and operative skill), and have not charity, I am nothing" (I Cor. xiii, 2). In the keen pursuit of scientific discovery, and thus the flight and feelings of a suffering creature may be forgotten. A doctor should add to the body some of the attributes of the broad-minded churchman. Sympathy and imagination, and both of these specially feminine properties should be preserved as valuable assets in our profession, and not transformed into callousness by contact with the patient and an understanding aspects of a doctor's life. Imagination should supply an insight into the mind of the patient and an understanding of the fears and anxieties of those who come to be cured. Without this conception of the patient's point of view the student may think only of the diagnostic problem and forget the human aspects. The influence of cheerfulness and of reasonable optimism on the sick should be ever borne in mind; yet this may easily be forgotten in the presence of doubt reserve even amounting to bad manners, really due to the patient's worries and self-consciousness. With a cheerful manner should be combined a degree of concentration sufficient to convince the patient that his condition is receiving serious attention; it is hardly necessary to carry this so far as to give the impression to every patient that he is the only person who counts in this world. Fact and self-observation, essentially feminine properties, are of great value in medical practice, and should therefore be preserved by medical women and not, as perhaps is sometimes the case, repressed or discarded by the more vigorously minded. As factors in rendering work congenial to women, this would appear to be an additional reason why most women are more suited for practice than for pure laboratory research.

intensely loyal to the British connexion. They are, moreover, extremely anxious to have young men of their own race trained as doctors and they have themselves subscribed over £11,000 to this project. In addition to this, one Sudan merchant has bequeathed all his property now in his lifetime to be held by trustees; the interest, a matter of £1,200 a year, is to be devoted to the maintenance of medical students during their period of study.

#### *Scope of the Project.*

The immediate intention is to train as assistant doctors young men selected from the final year students of the Gordon College.

The selection will be based on honesty of character, energy, and power of initiative, as well as on proficiency in their studies. They will have received a thoroughly sound secondary education including a good knowledge of English, which will be the sole medium of instruction. The number of entries each year will at first be limited to twelve. The period of instruction will be four years. During the first two years the instruction given will include the preliminary sciences and anatomy, histology, physiology, and materia medica. The last two years will be occupied with the purely professional subjects. Special emphasis will be laid on hygiene and tropical medicine.

Work in the out-patient department will commence from the first year. Students who have conscientiously carried out their course of studies and who have satisfied their teachers and their examiners that they have attained the required standard, will be awarded a diploma authorizing them to practise in the Sudan only.

The object aimed at will be to obtain thoroughly conscientious assistant doctors accurately trained up to a definite standard and absolutely reliable up to the limit of that standard, but who would not be expected or allowed to attempt the higher grade work of the highly trained physician or surgeon.

These assistant doctors will often be stationed in isolated posts, but they will be under the general direction and advice of British medical inspectors.

That the Sudan Arabs can be trained to be useful doctors has been shown by experiments carried out at Khartum Civil Hospital. A few selected youths have been trained at this hospital as assistant medical officers, and in spite of the impossibility of giving them a scientific medical training owing to the lack of laboratory accommodation and of the equipment necessary for a teaching school, and to the insufficient teaching staff available, a considerable proportion of these purely empirically trained assistant medical officers have proved themselves to be men of marked ability and have performed very valuable work in combating epidemics and in rendering simple surgical and medical assistance to the people among whom they have been working.

At a later date, when the pressing need for doctors has been met and a suitable teaching staff has been built up, it is proposed to extend the length of the curriculum to five years and to bring the standard of the curriculum and of the examinations up to the standard demanded by British medical schools; the preliminary sciences will by then be included in the curriculum of the Gordon College.

It is thus hoped in the not distant future to have a medical school at Khartum which will take a leading place in the civilizing and development of North-East Africa, and which, working in close liaison with the older schools of Europe and America, will produce really good scientific work.

#### *Facilities for Teaching.*

A medical school building is in course of construction, and will be completed by November next; it contains a lecture theatre and laboratories for the teaching of the preliminary sciences and of anatomy, physiology, and pathology. The site of this building is opposite to the Civil Hospital and only a few yards from it on the main road leading from the railway station to the Palace.

The clinical teaching, clerking, dressing, etc., will be carried on at the Khartum Civil Hospital, a well equipped modern hospital of a hundred beds with an x-ray installation and clinical laboratory. A new and well equipped out-patient department has just been added, so as to afford greater facilities for out-patient teaching.

#### *Teaching Staff.*

For the present the teaching will be carried out by the Government medical and scientific staff, including the director and staff of the Wellcome Tropical Research Laboratories, which are situated within ten minutes' walk of the medical school buildings. In addition to the Government staff a medical registrar will be appointed whose whole time will be spent on the medical school work.

It is recognized that this can only be a temporary arrangement for a few years, and that later it will be necessary to increase the whole-time teaching staff considerably.

#### *Need for the School.*

It has been pointed out that the object of the school is to build up a service of Sudanese doctors which will enable the diseases and epidemics of the Sudan to be dealt with more effectually both by medical and hygienic measures, and which will render it possible to establish the hygienic conditions necessary to enable the schemes of economic development at present in course of execution and their subsequent extensions to be carried out successfully.

At present there are immense areas throughout the Sudan, and especially in the southern regions, in which the population is completely out of reach of any hospital and cannot be visited by Government medical officers. In consequence the loss of life from untreated disease and unchecked epidemics is very great. In particular the following diseases call urgently for further medical and hygienic action:

(a) In the extreme south and south-west sleeping sickness is exacting a heavy toll from the population, and in the south-west, Bahr-el-Ghazal, this disease has increased greatly during the last few years. There is always the danger of it becoming acutely epidemic.

(b) On the Blue Nile kala-azar appears to be on the increase.

(c) In the southern Sudan also great numbers of the population are attacked by yaws and syphilis, and these diseases appear to be rapidly gaining ground.

(d) Bilharziasis, ankylostomiasis, and trachoma are widely spread in the northern and central Sudan, and it is essential to stamp out these diseases before they have got such a hold on the population as to render this practically impossible, as is the case in Egypt.

(e) The population of the central Sudan is annually prostrated with malaria, which is largely preventable.

As regards the economic development of the Sudan which has been referred to above, a dam is being built across the Blue Nile 170 miles south of Khartum, and 300,000 acres of the fertile Gezira plain will be placed under perennial irrigation for cotton cultivation. The railway also is being pushed through to Kassala so as to link up this potentially rich country with Port Sudan, thus enabling large areas of the fertile Gash delta to be brought under cotton cultivation on a profitable basis. The cotton-growing areas of the Sudan can be extended almost indefinitely. In the Gezira alone over a million acres of ideal cotton-growing land await development, and there are further enormous areas in Kassala Province and up the White Nile and Sobat rivers which will gradually be brought under cotton cultivation.

There is just sufficient man-power in the Sudan to meet the needs of this development, but none to spare. It is essential that there should be no wastage of man-power, and that there should be a steady increase of the population to meet the progressive development foreshadowed above. The whole success of this development, therefore, depends on adequate medical and hygienic arrangements being carried out, and this cannot be done without a largely increased supply of doctors.

In addition to these considerations it is confidently expected that an increase of doctors in the southern regions will greatly facilitate the administration of these partially pacified countries. The quickest and surest way to pacification and civilization in Central Africa is to increase enormously the number of doctors.

It is difficult to think of any other way in which such far-reaching results can be obtained for such a trifling expenditure, so much suffering relieved, so much work done towards enabling the great potential wealth of this country to be developed.

SOME CAUSES OF INTESTINAL OBSTRUCTION.\*

nerve impulses to the central nervous system. These in turn give rise to normal responses which are sensations and movements. The basis of the process is the physiological or functional unit of the nervous system.

Ill health, on the other hand, reveals itself by some disturbance of this process, and we are seeking to recognize the significance of these disturbances. Ill health is not in the organs of the body. When the nervous processes are disturbed the fact is usually recognized by the patient before any change in the organs can be demonstrated by the pathologist. Alterations in sensation occur which the patient recognizes as abnormal, and such alterations may be the first indication of the departure from normal health. Consequently there may be reflex phenomena which show up to recognize. Any part of the reflex arc, or of the anatomical basis of the physiological unit, may be the site of the disturbance, though some parts of it are more susceptible than others.

Our contention is that we must look for the first signs of ill health in the nervous regulating processes of the body. They are the basis of the vital activities and maintain the life of the organism as a unit. Disturbance of the vital processes is the first sign of ill health, and their failure is the ultimate cause of death.

1. Volunteers of the Small Intestine.

Volunteers of the small intestine is a very rare condition, and the whole of the jejunum and ileum may be involved, or only one loop may be affected. Tully Vaughan, as quoted in Rowlands and Turner's *Operations of Surgery*, has collected 21 cases. In several of these the difficulties were so great, and the appearances so puzzling, that the operators did not recognize the condition during operation. The following is a case of volvulus of the small intestine:

A man, aged 25, was admitted to a nursing home in November, 1920, on open touring car. Forty-eight hours previously he had been seized with violent pain in the abdomen, round the umbilicus, accompanied by vomiting. The pain never entirely subsided, but had violent attacks at intervals. He had vomited everything, and passed no stools. On admission he was in a very weak condition—temperature 97°, pulse 120. During the examination of the abdomen peristalsis was excited, and a coil of bowel could be felt below and to the right of the umbilicus. The abdomen was opened through the right rectus, and the

[illegible]

The case was of interest because of its rarity and its extraordinary cause, and also of the long interval between the cause and effect. It is condemnatory of the expectation of an attack there may lurk in the abdomen unsuspected for years, and it reminds one that after treatment of appendicitis, when he had had an attack of appendicitis, a young, athletic man, who had been well in the interval. The patient made an

There are two varieties of duodenal hernia—right and left—the left being the more common. The left hernia originates in the paraduodenal fossa of Landzert. Fritsch states that three conditions are necessary for the formation of a left duodenal hernia:

1. The existence of a fossa and its boundary folds.
2. The presence of the inferior mesenteric vein in the fold.
3. Sufficient mobility of the small intestine to permit its entry into the sac. The mouth of the sac may be two or three inches wide. The size of the hernia varies from that of a walnut to the size of a man's head, and may contain all the small intestines. The length of intestine may be as small as two inches.

Left duodenal hernia occupies at first the left and upper portion of the abdomen, but eventually may occupy nearly the entire cavity. In 1899 Moynihan collected 57 cases of left duodenal hernia. Diagnosis is rarely made, and the condition is discovered at operation for acute intestinal obstruction or at autopsy.

The following is a case of left duodenal hernia in a woman:

*History*.—The patient was healthy as a child. Her first illness was acute rheumatism at the age of 21. She was ill for three months, but eventually made a good recovery. Since that attack, until June, 1920, she enjoyed very good health, but was inclined to be conspicuous at times. She was not in the habit of taking aspirin, and the foot of a bed, and she had severe and sickening pains over her back since. Immediately after each meal, and without fail, she experienced a dull pain in the epigastric region, radiating to the umbilicus. Coincident with the pain was distension of the abdomen. The latter disappearing at the same time as the former. Since the accident she had been more conscientious, and had been compelled to take aspirin on alternate days, but she never vomited. This condition persisted until November 8th, 1920, when she became acutely ill. On that date the usual pain appeared after dinner, passing away in the usual time. About three-quarters of an hour afterwards she was seized with violent pain in the epigastric region, causing her to sink to the floor and roll about in agony. She had no vomiting on that occasion. The pain persisted for about two and a half hours, gradually disappearing. She leapt well and until the following night. On November 9th, 10th, and 11th, though she had slight continuous nausea, but no vomiting. Her diet was restricted to milk, and she noticed slight abdominal distension. The only actions of the bowels during this period were on the 12th another acute attack set in about noon. This time the pain persisted, abdominal distension became very marked, she continued very persistently, and no gases was passed.

*Condition on admission*.—She was admitted to hospital the morning about 10.30. Abdominal distension was marked. The pulse was tender, and the pain very severe. The pulses were imperceptible at the wrist, and collapse was intense. Vomiting and ceased. Immediate operation was decided upon, and under anaesthetic laparotomy revealed a large omental tumour, which was slightly movable, but not on respiration, and resonant on percussion. The lower border was on a level with the navel, and escaped from the sac along with the intestine. No attempt was made a rapid recovery. Though desperately ill for a day or two the patient died.

*Operation*.—The abdomen was undertaken with the hope that some manipulation, rapidly executed, might still arrest further growth. Operation was undertaken with the hope that some manipulation, rapidly executed, might still arrest further growth. Operation was undertaken with the hope that some manipulation, rapidly executed, might still arrest further growth.

## CORRESPONDENCE.

present stage of our knowledge. In the first place, it is both broad and non-committal. Mr. Fisher's term "chronic arthritis," while helpful in dealing with purely joint affections, does not associate it in any way with other manifestations of rheumatism, which, as is well known, are extraordinarily protean in character. Improvement of the "chronic arthritis," as the result of treatment, is commonly associated with improvement of other manifestations of the "rheumatic poison"—namely, muscular rheumatism, neuritic pains, etc. This frequent experience suggests the same etiological factor for all these conditions. In South Africa, while acute rheumatic fever is relatively uncommon, the various conditions which may be broadly grouped as chronic rheumatism are extremely common. It is also interesting to note that these conditions were especially in evidence immediately after the influenza epidemic, 1918.

My experience of "rheumatism" is derived from bacteriological investigation of cases and observing the results of treatment, especially with vaccines. The extraordinary frequency with which one finds in chronic cases of "rheumatism" various streptococcus groups, such as *S. haemolyticus*, *S. viridans*, *S. mucosus capsulatus*, in association with septic teeth and gums, or in cultures of nose and nasopharynx and tonsils, brings these organisms into prominence. The good results following vaccine treatment in these cases with both stock and autogenous vaccines prepared from these organisms lends further support to their etiological importance. The frequency with which organisms of the streptococcus group, derived from widely different sources, cause arthritis in rabbits, as shown by Topley and Weir, is significant.

It may well be that all cases of rheumatism—arthritis, neuritis, myositis—are due to bacterial invasion, the condition traumatic osteo-arthritis lends itself to the interpretation that it is due to bacterial invasion, the resulting intoxication being localized to tissues damaged by injury.

A useful analogy is furnished by the word "diabetes." Advances in our knowledge, such as the discovery of insulin, assist us to a better understanding of this subject, but these advances in no way prevent our appreciating the value of the word "diabetes," which does not in any way commit us to an explicit statement of the etiology of the disease, and so leaves the matter an open question.

To make my point clear, I personally prefer the term "chronic rheumatism" to the term "chronic arthritis." The tone and substance of Mr. Timbrell Fisher's paper can be productive of nothing but good, and should act as a stimulus to physician, surgeon, and pathologist alike to increase their labours to advance our knowledge of this complex and highly important subject.—I am, etc.,

J. PRATT-JOHNSON.

Johannesburg, Sept. 5th.

## CANNABIS INDICA: A "DANGEROUS DRUG."

SIR,—It is strange that cannabis indica, its preparations and derivatives, have not been included among the drugs of the Dangerous Drugs Act, and that after our long experience of India so little appears to be known about it. The deleterious effects of the drug are, I think, thoroughly realized in India now—in fact Indian hemp is the Indian "dope." In the press reference is usually made to it under the name "hashish." This is the preparation used by natives of the Near East, Turks, Egyptians, Arabs, etc., and it corresponds pretty closely to the Indian "ganja." In India the drug is consumed in three chief forms.

1. *Bhang*.—This is an infusion of the leaves, generally of the wild plant *Cannabis sativa* or *indica*, which is drunk especially during religious and other festivals, and ordinarily is a slightly stimulating drink much of the type of tea. Infusions, however, tend to become decoctions and to include ganja proper, especially in South India, and then the toxic effects of the drug become apparent. Macaulay in his essay on Clive refers to the use of bhang as a stimulant for attacking troops.

2. *Ganja*.—This is a stronger decoction of the cultivated plant, including the dried flowers to which a certain amount of gum resin is left adherent, and it has a definitely intoxicating effect. Its use is common among sadhus, fakirs, and religious devotees generally.

3. *Charas*.—This is the collected gum resin exuded by the flowering tops, and is by far the strongest and most dangerous preparation of Indian hemp used as a popular drug. It is, however, expensive, and is consequently consumed mainly by well-to-do addicts, especially in Northern India. Charas is usually smoked in a pipe (*chillum*), often as an addition to tobacco, and ganja is sometimes similarly taken.

I may add that a small amount of hemp is a fairly common ingredient of various sweetmeats.

The effects of the drug are detailed in all the well known textbooks, and that its abuse is a direct source of serious mental disorder is indisputable. This fact has been stressed in many official Indian publications, and has been discussed in the medical and lay press, and as the therapeutic value of cannabis indica is trifling when compared with most of the other medicines on the dangerous drugs list there appears to be no reason why its popular use should not be similarly banned.

In 17 to 20 per cent. of male admissions to the Indian mental hospitals and asylums the insanity is directly traceable to Indian hemp, but the vice is more prevalent in certain provinces than in others. I have seen no clear case among women of insanity from this cause. This drug has given rise to inquiry in other countries—for instance, Ceylon and East Africa, to the Governments of which I have, by request, furnished particulars.

The mental symptoms due to a bout are as a rule confusional, but this condition is not so regularly observed as it is when other deliriant poisons have been the cause of the mental disorder. In these ganja cases very often a characteristic wild maniacal excitement of an evanescent type results. The insane habitual consumer almost always exhibits maniacal-depressive symptoms tending rapidly to dementia.

In twenty-four years' experience in India I have seen only three cases of the use of the drug as a "dope" by Europeans. One of these was a well-to-do globe-trotter who had taken drugs all his life, and who had no particular interest in Indian hemp, except to obtain prolongation of time. Another was an excise inspector, who, when we first met, was compelled to turn his back, stoop, and view me from between his legs in order to see me in the standing position. His insanity was caused by ganja, and he recovered rapidly. The third was an habitual of the beach-comber type who became demented.

In my experience, the habit, even when of long standing, can be easily broken, and the craving and abstinence symptoms are slight. The vice of drug taking is a very uncommon one among Europeans in India, so that the small number of hemp cases I have quoted cannot serve as any guide to the probable incidence of the habit should the sale of Indian hemp continue unrestricted in England.—I am, etc.,

W. S. J. SHAW, Lieut.-Colonel I.M.S.

Bournemouth, Sept. 18th.

## THE ETIOLOGY OF CANCER.

SIR,—There is a widespread group of parasitic degenerate acari which has a wonderful power of producing new growths in the vegetable world. This group (the Eriophyidae) causes galls on the bramble, elm, lime, hazel, currant, and on other plants. It causes the well known "witches' brooms" on birch and other trees. It produces the strange disfiguring growths, green when young, black or brown when old, so common on salix trees around London. The *Demodex caninus*, which causes "mange" in dogs, belongs to this family, and so also does the *Demodex folliculorum*, an extremely common parasite on man. The *Demodex folliculorum* is universally believed to be harmless. But is it? The credentials of demodex should be examined.

If these parasites can cause such strange growths among vegetable cells, why not among animal cells? What takes place in the case of the salix tree is very interesting and suggestive. The acarus or mite (*Eriophyes*) attacks the female flowers by entering the carpels. The carpels, like the other structures of the flower, are modified, specialized foliage leaves, but under the influence of the mite they revert to a more primitive type. They become small, distorted foliage leaves, very numerous, and aggregated into a tumour-like mass.

OBITUARY.

Obituary.

HENRY DAWSON FARNELL, F.R.C.S.,  
Eastbourne.

HENRY DAWSON FARNELL, who died at Eastbourne on September 16th after a short illness, was born at Salisbury in 1852, studied medicine at University College, and became M.R.C.S. in 1874. He was house-surgeon at Liverpool Northern Hospital from 1875 to 1877, and in the latter year went to Eastbourne as assistant to Mr. R. Colgate, whose daughter he married in 1881. He had two sons and three daughters, all of whom survive; his wife died in 1918. In Eastbourne he soon became known as a brilliant surgeon, and his reputation extended far beyond the limits of the town. He became F.R.C.S. in 1885. He held many appointments, succeeding his father-in-law as medical officer to the Union Infirmary, a post which he held for several years, and being one of the original staff of the Princess Alice Memorial Hospital, an institution in which he took the deepest interest to the end of his life. (It is touching to note that in the announcements of his death friends are asked to send contributions to the Hospital instead of flowers to his funeral.) Mr. Farnell was appointed J.P. in 1895. During the war he was surgeon to the Eastbourne Military Hospital, and in charge of Urmston V.A.D. Hospital. In 1919 he was awarded the O.B.E., and in the same year became medical officer to All Saints' Convalescent Hospital.

No man can ever have held a higher place in the estimation of his professional brethren than H. D. Farnell. He was not only a great surgeon but above all a straight man, a man to be trusted implicitly. His patients loved him for his tender care and unselfish devotion; indeed it is no exaggeration to say that to know him was to love him. In the prime of his life Farnell was a very type of mental and bodily vigour, and his energy seemed almost incredible. Even in the last months, when a certain failure of health necessitated some slackening off of labour, he still clung to such work as was possible; on the very day of the seizure which was to prove fatal in so short a time, he took his seat on the Bench; and the first symptom of his illness occurred when he was parting from a patient. Thus he died as he would have wished, "in harness," and has left a void in the profession which will indeed be hard to fill. To the host of his friends the loss is irreparable.

We are indebted to Dr. ALEXANDER CRAIGMILE for an appreciation of his friend: Henry Dawson Farnell and I first met in the summer of 1875 at the Northern Hospital, Liverpool (now the David Lewis Northern Hospital), to which he came as senior house-surgeon, and I as house-physician. So began a friendship which lasted without a break till now. The Northern was at that time one of the chief accident hospitals in England, for to it were brought the majority of the casualties along the line of the northern docks, from the London and Lancashire Railway, and from the many sad cases of septicaemia and pyaemia lying there with rigors and profuse sweats and copious suppuration waiting the inevitable end, a picture quite unknown to the modern surgeon.

Now Farnell, who came straight from University College Hospital, where he had been under the influence of Marcus Beck, and with the sanction of his staff, introduced the antiseptic system to the Northern, and we were soon in the full swing of Lister's ritual, as it then existed—carbolic spray, layers of carbolic gauze for dressings, with carbolic between the outer layers, disinfection of instruments, hands, and so on. Presently a marked change took place in the wards; suppuration disappeared, compound fractures healed kindly, and septicaemia and pyaemia were known no more, and so Farnell had the great honour of first introducing antiseptic surgery and Lister's methods to Liverpool. The late Mr. Chauncey Puzey, one of the honorary surgeons, in his presidential address to the Liverpool Medical Institution many years after, paid a generous tribute to the work Farnell had done in this direction. Of his work in Eastbourne it is the province of others to speak; from the beginning we were drawn to one

another by mutual tastes in many things—especially in literature and politics. He was a great admirer of Sir Walter Scott, and on holidays spent together he used to quote favourite passages and pithy sayings from his favourite novels, citing one incident after another. He stayed with us for a week this summer in North Wales, and finding Scott's Journal—new to him—buried himself in it and forgot the inclement weather of May. All who knew him well were aware of the keen interest he took in motoring to new places, where an old church with famous monuments and brasses was sure to claim his attention, for he took the keenest pleasure in the history of his country and its old traditions, and knew nearly every cathedral well. It was a privilege and a joy to be with him and one of his family on these trips, not forgetting Carey, his faithful and devoted chauffeur. He was "the dearest friend and most unwearied spirit in doing courtesies," ever loyal and unselfish, and true to his principles, wherever they might lead him. If we can follow him in some measure, we also shall do well.

Universities and Colleges.

UNIVERSITY OF LIVERPOOL.  
Honorary Degrees.

IN connexion with the meeting of the British Association in the city the University of Liverpool conferred the honorary degree of D.Sc. upon the following eminent persons: Sir Ernest Rutherford, Professor Niels Bohr, Dr. E. H. Griffiths (formerly Vice-Chancellor of the University of Wales), Professor Gilbert Newton Lewis (professor of chemistry in the University of California), Dr. Ernst Johannes Schmidt of Copenhagen (noted for his researches in marine biology), and Dr. G. Elliot Smith (professor of anatomy in University College, London).

UNIVERSITY OF DURHAM.

At a Convocation held on Saturday, September 22nd, the following degrees were conferred:  
M.B., B.S.—L. S. Henry, L. F. O'Shaughnessy.

The Services.

MINISTRY OF PENSIONS.  
VOCATIONAL TRAINING.

1. THE Minister of Pensions announces that, with the consent of the Treasury, he has arranged for the scheme for vocational training of officers, nurses, and men suffering from tuberculosis, attributable to or still aggravated by service in the great war, which is at present confined in operation as regards men to residents in England, to be extended to similarly disabled men ordinarily resident in Wales, Scotland, Northern Ireland, or the Irish Free State.

This scheme provides for courses of vocational training combined with treatment at certain institutions for the treatment of tuberculosis. These courses, if satisfactorily completed, will, it is hoped, enable disabled men to become efficient workmen and to earn a livelihood. Application for admission to the training courses will be considered if the applicant is suffering from tuberculosis attributable to or still aggravated by service in the war, and if he is certified to be in consequence of that disability unable to follow his pre-war occupation or (without a course of training) any other suitable occupation and it is necessary that he should be trained for another occupation.

Scotland, Ireland, and Wales, and Officers and Nurses in England.

Application for such training may be made by men resident in Scotland, Ireland, and Wales, up to December 31st, 1923, and must be lodged in writing not later than that date with the local office of the Ministry of Pensions. Applications by officers and nurses may be made up to the same date, and must be lodged in writing not later than that date with the Commissioner of Medical Services of the Ministry of Pensions for the region in which they reside.

Engl. and.

2. The last date for making application for training by tuberculous men (that is, excluding officers and nurses) ordinarily resident in England has already passed except for: (a) men who have not been demobilized or discharged for more than a year; or (b) men who have been continuously under treatment since their discharge, and in receipt of treatment allowances; or (c) men who have endeavoured since discharge to resume their pre-war occupations or to enter some occupation equally remunerative, and have failed to do so (or to retain their positions) owing to a disability attributable to or aggravated by service in the war. Application in writing may be lodged by men in these categories up to December 31st, 1923.

Convalescent Centres.

The Minister of Pensions announces that officers, nurses, and men who have hitherto been eligible to apply for admission to

thorough teaching. If a man has not been efficiently taught midwifery he will, certainly at the commencement of his professional life, often have difficulty in determining whether a particular case of labour he is attending is normal or otherwise. The experience he accumulates is only at the expense of his patients, and in many cases woman pay most dearly for doing their duty to the community.

The whole difficulty in teaching obstetrics is that of obtaining sufficient material. There are far too few lying-in hospitals, and the few obstetric beds in general hospitals are often filled with difficult and abnormal cases. A medical practitioner can practically always get a bed for a medical or surgical emergency, can he for an obstetrical emergency? Certainly not, and yet the latter might easily be the more serious. In the medical and surgical wards one patient is available for the study of many students, but in the obstetrical wards one patient is only available for one student. A proper hospital obstetric service is an absolute essential to the efficient teaching of midwifery.

#### ANTE-NATAL TREATMENT.

The true conduct of labour commences with ante-natal treatment. We shall all agree that although the forceps on occasions must be used and should be used, the less frequently this instrument is employed the better. The proper way, and one might almost say the only way, to accomplish such a reduction is by efficient ante-natal supervision. No doctor should agree to attend a woman in labour unless he is prepared to examine her on occasions more especially in the last few weeks of pregnancy.

If medical students are not taught ante-natal supervision on pregnant patients in the out-patient abdominal palpation ward, when they go into practice, know how to do so properly, or how to obtain accurate information from such palpation, or will they even take the trouble to palpate? I think not. In the past they certainly had no such opportunities, and to-day these are very limited. Even now, it is not compulsory for a student to attend an ante-natal department, always supposing there is one. Many men do not mind admitting that they are not always sure whether the head of the child is engaged or not, and yet the head remains the best point where we have got. Moreover, the examinations one has to make. I fear I am not exaggerating when I say that many women start labour without their doctor having any real idea of how it will progress, because of this lack of ante-natal supervision.

The forceps is used most frequently for ineffectual pains and disproportion between the head and the pelvis. Proper ante-natal supervision, by getting the patient into as good a state of health as possible, can do many things to help the efficiency of the labour pains. Proper ante-natal examination will lead to the detection of gross disproportion between the head and the pelvis, of malpresentation, and of those cases of minor contraction in which the head of the child is not engaged when it should be—a knowledge of which may easily avoid the abuse of forceps.

#### THE OPERATION.

And now let us consider for a few minutes extraction of the child by the obstetric forceps as a surgical operation, rightly termed a major operation. It differs from most other operations in that it is so frequently performed by men who do not otherwise operate. A man in general practice, unless he so desires, has very little need to perform the usual surgical operations, but many of the operations in midwifery he has to perform whether he likes it or not, whilst the public expects him to use the forceps as a matter of course, and this, as I have said, without proper training. The medical man may be called upon to perform a difficult forceps operation the first night he is in practice, and in most cases he has no assistant to help him with the operation and no one but himself or the nurse to administer the chloroform; so that whilst as a fact his whole attention should be directed to the actual extraction, he has to occupy part of his time in administering the chloroform.

Again, it is not unfair to say that many men take infinitely more trouble over the smallest so-called surgical operation than they do over the forceps operation. Indiarubber gloves are worn, the area of operation, if covered with hair, is shaved, and it is prepared with some antiseptic, the parts concerned are surrounded with a sterile towel, while the operator wears a sterilized overall, and the assistance of an anaesthetist is obtained. I agree that it may be impossible to obtain an anaesthetist, but there is no reason why rubber gloves should not be carried in every midwifery bag, and there is no difficulty in shaving the vulva or in applying an antiseptic. In the majority of cases are in rubber gloves worn, or is the vulva shaved? I fear not; while the patient is delivered in a bed which perhaps says in the middle, whereas she should be on a table, or at any rate on a bed which does not sag. The doctor may or may not have a sterilized overall, and the patient may or may not be suitably protected with sterile

them. Apart from the question of judgement, with strict attention to asepsis and midwifery, a doctor, by carefully reading up the anatomy and method of procedure, can perform most operations without, at any rate, a disastrous result, but not so in obstetric surgery. It is impossible to sterilize the vagina, whilst the normally the interior of the uterus is in pregnancy and labour is sterile. It is therefore impossible to pass anything into the uterus, be it the fingers, hand, or the forceps, without potentially infecting it; and moreover, from the darkness, warmth, and seum present therein, it tries in its ability to encourage the growth of pathogenic organisms any suitably prepared culture tube in a bacteriological laboratory. Moreover, although the microscope in the vagina may cause no harm, when they are transplanted to a suitable soil in the uterus death may result.

If a non-operating practitioner contemplated performing a small operation and then found that a big one was necessary he would get help from an expert. The trouble is that, an ordinary pupil with the forceps having failed, the doctor does not realize that he is up against something serious. He does not get help, but pull all the harder. Again, it is not unfair to say that many men take infinitely more trouble over the smallest so-called surgical operation than they do over the forceps operation. Indiarubber gloves are worn, the area of operation, if covered with hair, is shaved, and it is prepared with some antiseptic, the parts concerned are surrounded with a sterile towel, while the operator wears a sterilized overall, and the assistance of an anaesthetist is obtained. I agree that it may be impossible to obtain an anaesthetist, but there is no reason why rubber gloves should not be carried in every midwifery bag, and there is no difficulty in shaving the vulva or in applying an antiseptic. In the majority of cases are in rubber gloves worn, or is the vulva shaved? I fear not; while the patient is delivered in a bed which perhaps says in the middle, whereas she should be on a table, or at any rate on a bed which does not sag. The doctor may or may not have a sterilized overall, and the patient may or may not be suitably protected with sterile

THE Department of Scientific and Industrial Research announces that a licence has been issued by the Board of Trade to the Research Association of British Flour Millers under the conditions laid down in the Government scheme for the encouragement of industrial research.

MR. W. HARRISON MARTINDALE, Ph.D., has prepared a new edition of the list of preparations prepared and stocked by W. Martindale, 10, New Cavendish Street, W.1. It is in a convenient form and has an index. The firm has agencies in many parts of the world, including Australia, New Zealand, and South Africa.

THE Academy of Sciences and Faculty of Medicine of Paris have each received a legacy of a million francs from the late Prince of Monaco.

MESSRS. BAILLIÈRE, TINDALL AND COX have issued a catalogue of books on dentistry, including periodical publications. The catalogue is classified and there are indices of subjects and authors.

PROFESSOR ERNEST SALKOWSKI, director of the chemical laboratory of the Berlin Charité Hospital, and one of the pioneers of physiological chemistry, has died at the age of 79.

## Letters, Notes, and Answers.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

As, owing to printing difficulties, the *JOURNAL* must be sent to press earlier than hitherto, it is essential that communications intended for the current issue should be received by the first post on Tuesday, and lengthy documents on Monday.

ACTIONS desiring reprints of their articles published in the *British Medical Journal* are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

In order to avoid delay, it is particularly requested that ALL letters on the editorial business of the *JOURNAL* be addressed to the Editor at the Office of the *British Medical Association* and *British Medical Journal*, 429, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR of the *British Medical Journal*, Aitiology Westrand, London; telephone, 2630, Gerrard.
2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), Articulate Westrand, London; telephone, 2630, Gerrard.
3. MEDICAL SECRETARY, Mediscera Westrand, London; telephone, 2630, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone, 4737, Dublin), and of the Scottish Office, 6, Rutland Square, Edinburgh (telegrams: *Associate, Edinburgh*; telephone, 4361, Central).

## QUERIES AND ANSWERS.

### CONGENITAL DEFORMITY.

COLONEL J. SMYTH, I.M.S. (ret.), writes: If Dr. John Walker will consult vol. iii of the *Transactions* of the South Indian and Madras Branch of the British Medical Association at page 113 (filed at the Association Library) he will find a case of congenital deformity resembling that published (p. 546) in the *JOURNAL* of the Association (September 22nd). I remember the case well. What struck one so forcibly was the very healthy condition of the limbless baby.

### INCOME TAX.

"C. P." borrowed £1,000 for his medical course; he is now in practice and this loan has to be reduced by the excess of his receipts over expenses. How does this affect his income tax?

\* \* \* If the transaction can be shown to be that "C. P." is discharging his indebtedness by the payment of a variable annuity then he can deduct tax from the payments he makes; if, however, and this is more likely, he is simply reducing the loan by such payments and is not in fact paying an "annuity" then he cannot deduct tax. In neither case can he treat the payments as deductions in computing his own income tax liability; if they constitute an annuity such deductions are expressly forbidden by the Acts; if they are repayments of loan then they are "capital" payments and do not affect his income tax liability.

"H. J. H." inquires whether he can treat as an expense the payment of interest at 5 per cent. on the unpaid portion of the price paid for his share of the practice, including book debts, and what book on income tax can be recommended.

\* \* \* No; the Income Tax Acts expressly forbid the deduction of annual interest in computing liability; the reason is that a person making such payments is entitled to deduct income

tax therefrom at the time of payment, so that that tax has to be included in the sum which he will pay to the Revenue.

Nelson's *Income Tax Guide* (T. Nelson and Sons, Ltd., price 2s.) gives useful assistance in preparing returns.

"H. F. B." bought a car in 1912 for £350 and sold it this year for £100, buying a car of similar make and power for £600.

\* \* \* He can regard as a professional expense of the year 1923 the cost of replacing the old car, which is £600 - £100 = £500.

## LETTERS, NOTES, ETC.

### AN UNFORTUNATE BROTHER.

A FORTNIGHT ago, under this heading, we published an appeal signed by medical practitioners in Mirfield asking for contributions to a fund to help Dr. F. A. Storr of that place, who, as a result of thrombosis of the right femoral artery, leading to gangrene, had to undergo amputation of the upper part of the thigh some time ago. He is now suffering from a recurrence of illness, and his already depleted financial resources are strained. The West Riding Medical Charitable Society has made him a gift, but it is hoped that members of the profession will contribute. Subscriptions may be sent to the London Joint City and Midland Bank, Limited (Mirfield Branch), or to one of the practitioners in Mirfield who sign the appeal—Drs. T. W. Sproule, Leslie J. Milne, H. W. Elwell, and H. J. Dawson.

### CANNABIS INDICA IN SMOKING TOBACCO.

MR. T. F. HUGH SMITH, F.R.C.S. (Farnham), writes with reference to the memorandum published on September 22nd (p. 521): The following reference occurs in *Among the Wild Tribes of the Afghan Frontier*, by the late T. L. Pennell, M.D., B.Sc., F.R.C.S., in describing the influence of the Afghan Mullah; this passage is found on page 119:

"He regards the smoking of tobacco as one of the works of the devil, and when the Mullah makes his visitation to some village there is a general scramble to hide away all the pipes; for not only would any that he found be publicly broken, but the owner would incur his displeasure. As the Afghans do not confine themselves to the soothing weed, but mix it up with a number of intoxicating and injurious substances, such as Indian hemp or charras, this attitude of the Mullah may be regarded in the light of a reform."

THE "BRITISH MEDICAL JOURNAL" IN GERMANY.

MR. HUGH RICHARDSON, Stockfield-on-Tyne, Northumberland, writes: A few copies of the *BRITISH MEDICAL JOURNAL* recently posted to the University Library at Gießen in Germany have been very cordially acknowledged. The message continues: "You will understand that the possession of this celebrated medical journal is now quite specially valuable to us, so much the more since we have the complete years from 1890 to 1913 in our library." Is it possible that any of your readers who have kept back numbers from 1914 to August, 1923, would like to offer these to complete the series? If so, please address the offer direct to Frl. Nora Brückmann, Hessische Universitäts Bibliothek, Gießen, Germany, without further mediation.

### CANCER AND CARIOUS TEETH.

DR. R. J. LOVE (Staplehurst, Kent) writes: I practised in Cape Province, South Africa for 14 years (1901-15) and during that time I do not remember having seen a case of cancer among the natives. Another fact which struck me was that the natives do not suffer from carious teeth. If a native does happen to get toothache he will trudge to the nearest dentist or doctor, perhaps 30 miles away, to have it extracted. Since I returned to England I have seen quite a number of cases of cancer and they all suffered from carious teeth. Carious teeth are on the increase and so is cancer, and I put forward the theory that the carious teeth are the cause of cancer. I shall be glad if someone who has had the opportunity of observing large numbers of cases will contradict the above if my theory is not borne out.

### SCANDINAVIAN MEDICAL JOURNALS.

In our last issue (p. 533) we gave some particulars of Scandinavian medical journals. Messrs. Baillière, Tindall and Cox (8, Henrietta Street, London, W.C.2) inform us that they are acting as English agents for the *Acta Gynaecologica*, and can accept subscriptions and arrange for the supply of any other publications in that series.

### A WARNING.

DR. M. J. HORGAN (Nottingham) writes to advise medical men interested in Ireland to be cautious in their dealings with a young man seeking to dispose of a copy of *The Story of the Irish Race* by S. MacManus. The book is published by the O'Malley Publishing Company, Donegal, and intending purchasers might do well to communicate with them direct.

### VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 29, 32, 33, 34, and 35 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 30 and 31.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 145.

the organic hypertonus is only slowly affected, and to a slight extent. The functional hypertonus returns to normal during sleep. The author has shown that also early in the morning, before breakfast, in the horizontal position, the blood pressure is lowest, and in the first stage is of the normal height, though during the day it may be greatly increased. If the early morning blood pressure is increased the difference between it and the blood pressure during the day indicates how much is due to organic causes. The prognosis is most unfavourable where the fasting blood pressure is as high as, or even higher than, that during the day.

#### Diabetes and Syphilis.

231. J. A. ROORDA SMIT (*Nederl. Tijdschr. v. Geneesk.*, July 28th, 1923, p. 345) states that while Rollo in 1798 was the first to suggest a special diet for diabetic patients, Watts in 1849 was the first to show that diabetes might be caused by syphilis, and obtained considerable improvement with mercury in a patient suffering from diabetes insipidus. In 1860 Leudet treated a patient with potassium iodide who was passing 8 to 10 litres of urine a day containing a large quantity of glucose. The patient recovered, but later a fatal relapse took place, the urine on this occasion not containing any sugar. At the autopsy a syphiloma was found in the fourth ventricle. Jullien's patient, a man aged 29, had secondary syphilis, diabetes mellitus, and was impotent. All the symptoms disappeared after six weeks' treatment with mercury. Dub's patient had severe diabetes mellitus, and was cured by potassium iodide. Other cases illustrating the association between diabetes and syphilis have been recorded by Cyon (1864), Perroud (1869), Moissonnet (1876), Fournier (1879), Frerichs (1884), Lemonnier (1888), Pospelow (1894), Regnier (1919), and Carnot and Harvier (1920). Smit, from his personal experience, is inclined to regard syphilis as one of the chief causes of all forms of diabetes. During the last few years he has seen 12 cases of the association of diabetes mellitus or insipidus with syphilis. In one case, in which the diabetes was not in any way affected by mercurial treatment, syphilis was merely a concurrent disease, while in the remaining 11 it was obviously the cause of diabetes. One of the 11 cases died without specific treatment, and the results of specific treatment in the other 10 cases were as follows: (1) Two patients with diabetes insipidus recovered completely. (2) Three patients recovered completely from diabetes mellitus as well as from diabetes insipidus which developed later. (3) One case of diabetes mellitus recovered completely under treatment with potassium iodide. (4) One patient with diabetes and a positive Cammidge reaction recovered completely and the Cammidge reaction became negative. (5) In one patient who had a history of syphilis the diabetes was not cured by specific treatment. (6) Two patients showed considerable improvement, though the diabetes was not completely cured. In one of these this result was probably due to inadequate treatment, and in the other to parasymphilitic changes in the brain.

#### Surgery.

##### 235. Post-traumatic Epilepsy and Repair of the Dura Mater.

H. BURCKHARDT (*Zentralbl. f. Chir.*, August 18th, 1923, p. 1277) discusses the generally recognized fact that epilepsy may supervene after apparently complete recovery from a fracture of the skull or other laceration of the dura mater. He describes the normal anatomy of the cranial contents, the brain being supported on a "water cushion," and compares it with the pathological condition in which the brain becomes adherent to the torn dura mater, and as the cicatrix contracts that portion of the brain is fixed to the dura and subjacent bone and necessarily undergoes some distortion. This fixation of the cerebral surface to the skull explains the slow development of epilepsy, as firm cicatricial contraction at describes the case of a man whose skull was fractured in a railway collision. Two years afterwards he developed epilepsy. The attacks increased in frequency, and an operation of the site of the fracture was performed; a resection of the bone was exposed and the thickened dura was dissected off; an osteoplastic flap was raised with a large enough to secure an ample blood supply. The flap of this flap was attached to the edges of the defect, from which the old cicatrix had been dissected, repair completed by transplantation of fat and fascia. It further development of adhesions. Burckhardt ends that when planning the osteoplastic flap care be taken to preserve large arteries such as the middle meningeal.

##### The Advantages of Cholecystectomy.

236. DE WITT STETTEN (*Amer. Journ. Med. Sci.*, July, 1923, p. 1) considers that it is justifiable to assume that the retained gall bladder, at least one that has been drained, is a menace to the health if not the life of the patient. It is a universal opinion that a gall bladder seriously damaged, the seat of malignant disease, or in one whose cystic duct is obliterated, should be removed. In the other and the great bulk of gall bladder operations there is still a considerable divergence of opinion. Of the complications of the retained gall bladder the formation of a persistent fistula is one of the most common, whilst stones that have been overlooked, adhesions, or ventral herniae are by no means uncommon. The author advises a primary cholecystectomy, if at all possible, irrespective of the degree of structural change in the gall bladder itself. Where this cannot be done and a cholecystostomy is performed, the gall bladder should be removed later. Re-operation is in many cases not a matter of choice but of compulsion. The only exception is in irremediable occlusion of the common duct, such as carcinoma or stricture. In chronic pancreatitis with jaundice cholecystostomy should be performed; when the fistula has closed and the patency of the common duct is assured, secondary cholecystectomy should be undertaken. In chronic pancreatitis without jaundice cholecystectomy is the operation indicated. In cases of "silent" gall stones where the gall bladder appears normal he practises removal of the gall bladder without drainage. He has failed to see any harm come from the absence of the gall bladder, and in many cases it is worse than functionless. After removal the period of convalescence is shorter and the wound heals more rapidly, whilst adhesions are not so liable to form, particularly so in the absence of drainage.

##### 237. Treatment of Fractures of the Malar Bone and Zygoma.

R. DUCHANGE (*Journ. de Méd. de Bordeaux*, August 10th, 1923, p. 557) describes the anatomical relations of the malar and temporal bones and reviews the literature on this subject. The malar may be displaced outwards or inwards; outward displacements are very rare, but several cases are cited. When the malar is forced inwards the adjacent bones are necessarily involved, but Hamilton stated that the malar may be forced inwards from 4 to 6 mm. without fracture. Flattening of the cheek alone does not necessarily indicate a fracture: there must be deformity, mobility, and crepitus; these are usually associated with pain. Oedema quickly masks the flattening of the cheek, and may obscure the diagnosis. Mobility and crepitus may be absent. Pain especially on palpation, is usually severe. Asymmetry of the two suborbital borders is still more important. Duchange states that trismus occurs immediately in fractures of the zygoma (due to injury to the masseter), while in fracture of the malar it comes on more slowly, and when that bone alone is involved, disappears quickly. There may be also epistaxis and exophthalmos and subconjunctival ecchymosis. Treatment is useless if delayed for a few days. Duchange describes the various methods recommended by Malgaigne, Hamilton, Murphy, and other surgeons for (1) reduction of the fracture and (2) retention in position. The latter introduced a modification of lion forceps (illustrated). The four sharp points are long enough to seize the malar, without incisions in the soft tissues, while the instrument is strong enough to firmly grip the upper and lower borders of the bone, which is then replaced. The punctures made by the jaws of the forceps heal without scarring. Compound fractures—for example, severe gunshot wounds involving the malar or zygoma—must be treated on general lines. These wounds may result in extensive deformity, especially ectropion of the lower eyelid, while the optic nerve and the second branch (infraorbital) of the fifth nerve may be involved. Duchange claims that his method of reduction avoids incisions of the buccal mucosa, which necessarily increase the danger of sepsis.

##### Stenosis of the Bile Ducts.

238. M. A. GOSSET (*Bull. et Mém. Soc. de Chir. de Paris*, May 1st, 1923, p. 604) reminds us that wounds of the bile ducts may at operation heal easily. In the majority of cases cholecystotomy is carried out on a duct that is more or less dilated, and under such conditions cicatrization and contraction of the scar is of no consequence. If, however, the duct be not dilated healing of the wound may result in stenosis or even obliteration of the duct. He describes a case where, after drainage of the duct, on removing the drain contraction of the scar tissue produced complete stenosis of the bile duct. Operative treatment was decided upon and exploration showed that there was an injury to the ducts at the junction of the cystic and common ducts. A probe passed freely

Our attitude towards the management of labour has like-  
wise been that of perfecting the substitute for the natural  
powers—the bony biceps of the attendant exerted through  
the midwifery forceps—at which, as in the case of artificial  
feeding, we have obtained success, but also along the wrong  
lines. So long as our sole idea is that labour, if protracted,  
can always be terminated artificially, we are in the same  
position as those who at once resort to artificial feeding, if  
the baby is not progressing, instead of trying to discover  
and remove the causes of failure at the breast. That out-  
of-date method was clearly another example of relying solely  
on the second line of defence, and abuse of forceps will con-  
tinue till a like change comes about in our attitude of mind  
towards midwifery.

Let us now see what changes the adoption of the prin-  
ciple that the maintenance of the physiological is to be our  
first objective in midwifery practice will make. In the first  
place, it involves a shifting of the centre of gravity of  
medical practice from mere attendance on labour, par-  
ticularly its finishing stages, to the general supervision  
involving the presence of the doctor at the birth. Much of  
before, during, and after labour, but not necessarily  
necessarily its finishing stages, to the general supervision  
this has already been accepted with the development of ante-  
natal supervision. Suppose as a result of that supervision  
the malpresentations, misfits between the head and the  
pelvis, and other foreseeable complications in labour have  
been excluded, we are left with by far the most frequent  
cases in which the forceps is used—those of slight  
nutation in action with a delayed second stage.

Time will not allow of a discussion of what is, and may  
be, possible to diminish the need for the artificial termina-  
tion of labour, and in 1921 I discussed this aspect of the  
inexorable forceps problem and can refer you to it;  
though the matter of that paper was excellent in its  
so unattractive that I am sure none of you read it. I might,  
supervision must include a study of the individual charac-  
teristics of each patient and all attempt to understand her  
temperament and her mental attitude to what is before her.  
It should also convey the assurance that she is a normal  
woman who will have a natural labour and should remove  
all suggestion of failure from her mind. The chances of  
success are much greater in institution management—an  
additional argument to that advanced by your President—  
because of its better provision for surgical technique. The  
atmosphere in a hospital or nursing home with its assurance  
of success is an important factor in labour, as in the case of  
breast-feeding. The securing of the right atmosphere is a  
with her playing the chief part as target-shooter and sur-  
rounded by worrying and fussy relatives. The avoidance  
of fatigue is another point, for the uterus of an exhausted  
woman will not function efficiently. Loss of sleep, lack of  
food, and, most of all, the fatigue that comes with long-  
continued pain, are among the common causes of exhaus-  
tion, producing restlessness and loss of self-control. To my  
mind a knowledge of how and when to give relief to the  
exhausted woman is a big factor in lessening a resort to the  
forceps delivery.

In the conduct of the labour itself the object of the medical  
attendant should be as much as possible in the direction of  
supervision, and supervision that is kept in the background  
as much as possible. Stated that everything is normal,  
the actual labour can be left to a midwife on her mettle to  
make the obstetrician's methods a success, and the patient  
should be encouraged to deliver herself naturally. Care  
to the extreme of refusing to recognize failure and to post-  
pone forceps delivery to the detriment of mother and infant.  
The choice of a midwife is extremely important, and it is  
essential that she should be enthusiastic and show no lack  
of confidence or over-anxiety, which would be at once  
reflected in the patient. Another reason for the medical  
supervision being kept in the background is that the presence  
of a doctor with a bottle of chloroform and a bag of clinking  
instruments is often too strong a suggestion of a speedy end,  
without further effort to encourage natural delivery. It  
may be argued that toxic drugs used to "dope" a patient  
are less physiological than terminating the labour by forceps  
without drugs, but there is clearly a middle course. Treat-

ment by sedatives is more rational, in that the difficulty  
with most of these patients is that they are over-sensitive and  
highly strung and fatigued easily, for which these drugs are  
the correct treatment.  
Pain is another important point which has been  
neglected and doubtless increases the incidence of instru-  
mental cases. The natural position is a squatting one, and  
I would like to hear if any of you have tried that posture  
in the hope of increasing the chances of natural expulsion.  
Then there is the question of pituitrin and other drugs to  
stimulate the uterus when there is a little further effort  
required to complete expulsion. I think, however, that I  
have probably said enough to give at any rate an indication  
of the attitude I consider necessary to limit the abuse of  
forceps. I recognize clearly that in the case of ordinary  
domesticity practice it is much more difficult than in hos-  
pital; but I would urge that there is no reason why an  
attempt should not be made to diminish the excessive use of  
artificial means of delivery.  
The patients have a big say in the matter: they have  
engaged the doctor and expect from him an expenditure of  
time and skill for fees that are by no means equivalent,  
and the tendency of the profession has been to cut the loss  
by time-saving devices which are equally welcome to the  
patient herself.  
If, however, pleasing to recognize that every year there  
is a greater tendency to employ midwives under medical  
supervision for normal labour, and to my mind this is one  
of the most hopeful indications for lessening the abuse of  
forceps, for the incidence is always less in women delivered  
by midwives than in those delivered by doctors.  
Though you may plead *force majeure*—the exigencies and  
demands of practice—you all recognize that the forceps rate  
in private practice is excessive, and my contention is that  
we will never get away from this everlasting and world-  
wide controversy on the abuse of forceps until the attitude  
of mind that is satisfied with—or still worse, glorifies in—  
present conditions is corrected, and the falling back on your  
second line is recognized as a failure to hold the first. When  
that first line has been strengthened, you will find it a more  
tenable position than you thought.

DISCUSSION.

DR. JAMES HENRY (Glasgow) said that, while agreeing  
with the conduct of a forceps case should be regarded as a  
surgical operation, he wondered how many surgeons would  
operate under the conditions which surrounded a woman in  
industrial practice. He hoped that in future students  
would be required to supervise their "indoor" cases from  
the beginning of labour, and not only from the time the head  
reached the perineum. Then they would learn to recognize  
that the mother could continue in labour not for a certain  
number of hours, but until danger threatened mother and  
child. This would also give more opportunity for the  
recognition of abnormalities, whether of the pelvis or of  
presentation. Improved teaching would not, however,  
eliminate all the difficulties—there were still the psychology  
of the patient to be considered and the amount of time  
which a busy practitioner could devote to a maternity case.  
They should all aim at the "hospitalization" of maternity  
cases, and in that way they would not only eliminate the  
repressing factors referred to by Dr. Baird, but they  
would have the supervision of the cases by people with no  
other distant duties to perform, while, should the applica-  
tion of forceps become necessary, the proper conditions  
would be readily accessible.

Dr. R. KILSON Ford (Portsmouth) doubted whether,  
unless accommodation were provided by a specific hospital,  
it would be justifiable to allocate beds in a voluntary hospital  
for purely obstetric cases. He pleaded for a better use of  
existing institutions, such as the Poor Law infirmaries,  
which should be if possible placed under the administration  
of the medical officer of health for the district. There should  
be more comprehensive ante-natal treatment, and all these  
facilities should be made available for the institution of

cases operated on by experienced operators has caused perforation of the uterus. Strassmann's operation, consisting of removal of the inner wall and the uniting of each uterine half together so as to make one uterus in place of two, is recommended, and two cases are described, whereby one was relieved of menorrhagia and the other of severe dysmenorrhoea by such an operation.

#### 214. The Origin of "Tar Cysts" of the Ovaries.

B. NYSTRÖM (*Finska Läkarsällskapets Handlingar*, July-August, 1923, p. 433) has studied the origin of "tar cysts" of the ovaries (haematocystis plicea ovarii), 80 cases of which have been observed at Engström's hospital in the period 1890-1917. During this period considerably more than 4,000 laparotomies were performed at the same hospital. It has recently been suggested that these cysts are due to the existence within the ovaries of islands of endometrium which secrete a fluid resembling that of menstruation. The author has examined microscopically the walls of numerous such cysts, but has never found these hypothetical islands of endometrium. In no case was there a history of direct trauma in the neighbourhood of the ovaries, but there were three patients who associated the onset of their symptoms with severe bodily exertion. In as great a proportion as 86.3 per cent. there was a history of more or less regular sexual intercourse, and it is conceivable that such intercourse plays a part in the genesis of this condition. Of the married patients, 31.8 per cent. were nulliparae, and in more than a quarter of all the cases the disease was bilateral.

### Pathology.

#### 215. The Agglutination Reaction in Pregnant Women Suffering from Tuberculosis.

In tuberculosis the agglutinin titre of the serum varies with the course of the disease; a low titre—1 in 5—or the disappearance of agglutinins from the serum are both of bad prognostic import; a high titre—1 in 20 or 1 in 40—is of better prognostic significance, being met with in the fibrous forms or in the resistant phases of the advancing form. P. COURMONT and PAPACOSTAS (*C. R. Soc. de Biologie*, July 21st, 1923, p. 521) have applied this knowledge to the study of the variations in the agglutinin titre which occur in pregnant women who are suffering from pulmonary tuberculosis. Estimations of the agglutinin content of the patient's serum were made during the later months of pregnancy and from fourteen to sixty-eight days following delivery. Altogether 14 cases are recorded. Of these, 4 showed a low titre before, and a low or even falling titre after, parturition. In two instances the patients died; in the other two the disease advanced rapidly after delivery. In the remaining 10 patients the titre of the serum was generally fairly high before delivery, and remained high, or actually rose, afterwards. All of these patients did remarkably well. The authors conclude, therefore, that a low or falling titre before or after parturition is of bad prognostic import, whereas a high or rising titre is distinctly favourable. Cuterebraeactions carried out at the same time as the agglutination reaction failed to show any marked correlation with the agglutinin titre, and cannot be used to evaluate the patient's prognosis.

#### Inheritance of Cancer.

W. F. WASSINK and C. P. WASSINK VAN RAAMSDONK (*Nederl. Tijdschr. v. Geneesk.*, July 28th, 1923, p. 326) investigated the family histories of patients with various forms of cancer at the Antoni van Leeuwenhoek Hospital, Amsterdam, with the following results: 258 patients with mammary cancer had 102 other members of their families suffering from some form of cancer, which in 40 cases, or 39 per cent., was cancer of the breast; 274 patients with uterine cancer had 66 relatives with some form of cancer, which in 24 cases, or 36 per cent., was cancer of the uterus; 247 patients with cancer of the skin had 53 relatives with some form of cancer, which in 17 cases, or 32 per cent., was cancer of the skin; 46 patients with cancer of the lip had 10 relatives with some form of cancer, which in 5 cases, or 50 per cent., was cancer of the lip; 69 patients with cancer of the tongue had 9 relatives with some form of cancer, which in 2 cases, or 22 per cent., was cancer of the tongue. On the other hand, there were 89 patients with cancer of the mouth who had 19 relatives with some form of cancer, but none with cancer of the mouth; and 110 patients with cancer of the larynx had 31 relatives with some form of cancer, which in only 3 cases, or 9 per cent., affected the larynx. These figures on the whole show a pronounced tendency for the same organ to be affected by cancer in certain families. The more or less complete absence of any such tendency in the cases of cancer of the mouth and larynx may indicate that the localization of cancer in these situations is not due to inheritance but to such irritants as tobacco and alcohol.

#### Complications of Pneumonia.

217. H. M. FEINBLATT (*Boston Med. and Surg. Journ.*, July 28th, 1923, p. 136), from a post-mortem pathological and bacteriological analysis of 139 cases of lobar pneumonia and 41 cases of bronchopneumonia, found, in the case of lobar pneumonia, that the principal complications were empyema (38.1 per cent.), purulent pericarditis (17.2 per cent.), toxic nephrosis (10.7 per cent.), fibrinous pleurisy (9.3 per cent.), and cardiac dilatation (8.6 per cent.); and of the infecting organisms the pneumococcus alone was responsible in 91.7 per cent. of the cases, the streptococcus in 5.8 per cent., and the two combined in 2.3 per cent. In bronchopneumonia the principal complications were empyema (9.7 per cent.), cardiac dilatation (9.7 per cent.), toxic nephrosis (7.3 per cent.), and cranial sinus empyema (7.3 per cent.); and of the infecting organisms the streptococcus alone was responsible in 34.7 per cent. of the cases, the pneumococcus alone in 21.7 per cent., the tubercle bacillus in 13 per cent., while the streptococcus and pneumococcus together were the causative organisms in 8.7 per cent., the streptococcus and *B. influenzae* in 8.7 per cent., the pneumococcus and *B. influenzae* in 8.7 per cent., and the streptococcus and staphylococcus in 4.3 per cent.

#### 218. Catalase in Bacteria: Its Relation to Anaerobiosis.

The peculiar fact that the true anaerobes are unable to thrive in the presence of air receives an explanation from the work of ANNE BARBARA CALLOW (*Journ. of Path. and Bact.*, July, 1923, pp. 320-325), who estimated the catalase content of nine anaerobes and twelve aerobes and found that none of the anaerobes investigated gave off gas when treated with hydrogen peroxide, whereas all the aerobes investigated were shown to contain catalase with the exception of streptococci. The explanation suggested is that in the presence of air anaerobes take up oxygen, the latter assisting in the formation of a substance which either inhibits growth or kills the cell. According to Wieland's theory of respiration water is decomposed by an oxidoreductase into hydroxyl and hydrogen ions, the latter combining with the oxygen of the air to form hydrogen peroxide, which is at once decomposed by the enzyme catalase into water and molecular oxygen. In the absence of catalase the hydrogen peroxide would accumulate and kill the cell, and since anaerobes do not develop, the cells might be killed by the cumulative effect of hydrogen peroxide. In the absence of air no hydrogen peroxide would be formed and anaerobes would be able to develop. If the lack of catalase in anaerobes were indeed the cause of their inability to grow in the presence of air, it might be supposed that if a culture of an anaerobe were exposed to the air hydrogen peroxide would be formed, and repeated attempts to detect this substance in anaerobic cultures which had been left in contact with air or oxygen for various periods of time gave negative results. Since anaerobes contain no catalase it was thought possible that the addition of catalase to the medium might induce anaerobes to grow in the presence of air, but no conclusive evidence that anaerobes are able to grow aerobically in the presence of catalase was obtained.

#### Studies on Pneumococcus Immunity.

249. R. L. CECIL and G. I. STEFFEN (*Journ. Exper. Med.*, Aug. 1923, p. 149) have been studying the active immunity conferred on monkeys to pneumonia by the administration of monovalent vaccines. They previously showed that it was possible to protect these animals against experimental pneumococcus (Type I) pneumonia by either subcutaneous or intravenous injection of pneumococcus (Type I) vaccine; they showed, too, that in response to this vaccination protective substances appeared in the blood. This work has now been extended to the three other types of pneumococcus. Monkeys were prepared by the subcutaneous injection, at five to seven-day intervals, of a saline vaccine; the total dosage varied from 120 to 200 billion organisms. Two to three weeks after the last injection the monkeys, together with an unvaccinated control, were inoculated intratracheally with living pneumococci, the same organism being used for this purpose as was used for the preparation of the vaccine. The temperatures of the animals were taken twice daily. The leucocyte counts and blood cultures were made once daily. Those animals which had not died in the meantime were killed from the fifth to the ninth day, and complete post-mortem examinations conducted. The results with pneumococcus Types II and IV were quite definite; in every case the vaccinated animals failed to develop pneumonia, while the control animals did so. With Type III, on the other hand, the protection was not so complete; in a series of five experiments four out of eight vaccinated monkeys came down with disease, showing that vaccination is successful in 50 per cent. of the cases. In none of the monkeys vaccinated with either of the three types was it possible to demonstrate the presence of protective substances in the blood.

[illegible]

Dr. T. G. Evans (Beckington) protested against the character given to the general practitioner by Mr. Compans Berkeley. He never went to a case without gloves and axis-traction forceps. He had never attempted to rotate a wife for forceps, nor had seen anyone else try to do so. He would like to know what was the alternative to forceps in the case of prolonged labour, with the head in the pelvis. He reminded the Section of the danger of subsequent puerperal infection after Caesarean section from rupture of the uterine scar.

Dr. W. R. Grove (St. Ives) did not think that anyone could fail to agree that Nature was the best obstetrician. In nine out of ten delayed cases the delay could be traced to emotional causes. To combat fatigue he much preferred opium pills to morphia. As regards posture, he certainly thought that lying on the back helped the head to descend in the right direction and that the left-sided position was a hindrance. He had no use for gloves—it was just as easy to touch unclean objects with gloves as with the bare hands. He put his trust in antiseptic lotion, and strongly recommended one made up of Ipsol 2 drachms, and either half an ounce, and methylated spirit to four ounces.

Dr. C. J. Borchs (Cattord), speaking as a general practitioner, thought that the high ideals of Mr. Berkeley and might beseech their patients to come for ante-natal examination, but they would not do so. He did not see how one could gauge the amount of force necessary to use in a forceps case until one had tried. People in hospital would accept any treatment from a specialist or anyone they thought was a specialist, but they and their relatives would not submit to the same in their own homes. The public would have to be educated. If Mr. Comyns Berkeley and Dr. Farnham were right the general practitioner should never do any midwifery at all.

Dr. Lewis (Southport) agreed that gloves might be a positive danger in midwifery practice. It was becoming more and more common to call the doctor only in emergency; hence the number of forceps cases were relatively higher than they used to be. He thought that much of the damage done by the forceps was due to ignorance of the proper method of application; he had himself seen on two occasions an effort made to slip in the blades back to front.

The President, while agreeing with the views expressed in the brilliant paper which opened the discussion, felt very much in sympathy with the difficulty in which the practitioner was placed in regard to the forepains question. On the one hand there were his teachers praying him to be circumspect and moderate, and on the other an ignorant public urging him to interfere at the earliest opportunity. Time was short and the life of the patient was at stake. The payment for the midwifery cases was too small and there were more and more pressing and the shortening of labour. He had maintained and purchased for many years that midwifery was a branch of surgery and must be recognized as such both by the profession and the public before the three capital necessities for its proper practice could be obtained—adequate conditions, adequate assistance, and adequate payment. The looseness of a well known phrase common to almost all teachers and text-books—"forepains should not be dropped until the cervix is fully dilated"—was responsible, he thought, for much harm. For what was "full dilatation of the cervix"? It was relative to the size of the dimensions of the presenting part, which varied in different cases and were impossible to measure in any reverse. Therefore, that the only real proof that the cervix was dilated to allow the presenting part to pass easily through it was that the presenting part had already passed through it. But this was not expressed in the loose phrase he criticized, but rather some indefinite measurement in inches or centimeters as a ratio of comparison between the size of the cervix as felt and the head of the child as the practitioner imagined it to be. The outcome was that forepains were frequently applied when the head was still in the cervix, with the result that the diameters of the presenting part were increased all round by the thickness of the cervical tissue, and this became an important point between the head and the bone an impaction was produced in a pelvis which of itself was entirely large enough for labour to take place normally in. The teachers' physiology should be tightened up, and the words "Until the cervix is fully dilated" replaced by "Until the head has come through the cervix." He thought that dilatation was still failure to deliver, then performing with forceps less harm than persisting with forepains.

Dr. C. E. Docavatz (Chupar, Eñife) said that he spoke as a heretic in respect of the modern doctrine of non-interference. He had much enjoyed Mr. Comyns Berkeley's address, but there was a set of conditions in which the forcepts was very frequently used that had so far been ignored by all the speakers. Stress had been laid on the value of Caesarean section, of x-ray work in pre-natal examination, and other resources available in the great centres of civilization and nowhere else. He would invite them to come with him to some lonely spot very far from these resources, to where the country doctor had to solve the problem by himself aided by an old woman, probably deaf, as his assistant. His methods were more modern than might be supposed. Mr. Berkeley had advised the use of rubber gloves and of axis-traction forcepts, if any. He would say that both of these had been in common use with them for many years. The forcepts should certainly not be applied until the last stage was completely over and till, say, two hours in a multipara and half an hour more in a primipara, when, if no progress was being made, there was no point in waiting longer. After all, the relief forcepts does not seem to be one of their duties. If the forcepts does appear to be decided upon the vulva and perineum were again thoroughly disinfected, anaesthesia was begun, and the patient seen through the dangerous period of the chloroform sleep before handling over the handkerchief to the old woman. A clean tunic was put on, the hands were sterilized as for any major operation, gloves boiled with the forcepts in the sterilizer were put on, and the operation proceeded? Mr. Berkeley had spoken of the dangers of sepsis, of ruptured perineum, and of prolapse. What were the results? Mr. Berkeley had spoken of the

improbable. Nevertheless the tradition of maternal ancestors (feminine heredity) and its social influence on the early life of a generation that has witnessed the wide opening of careers to women cannot be neutralized at once, and its effects may persist for some time. That women as a class are inherently more law-abiding, more subject to what they regard as conventional, and more conservative might reasonably be interpreted as the outcome of long-continued subordination to men's ascendancy. More than a hundred years ago Sydney Smith<sup>1</sup> laughed at the idea that there was any inborn difference of intellectual capacity between men and women and argued that the conditions of education were entirely responsible for the existing differences. Further, in the Report of the Board of Education's Consultative Committee on the Differentiation of the Curricula for Boys and Girls respectively in Secondary Schools (1923) the opinion is expressed that there is little difference in intellectual capacity between the two sexes, though there are noticeable divergencies in emotional response as indicated by the degree of interest evinced for various studies, and that on the whole the apparent differences revealed up to the present by psychological inquiry would not seem to justify any serious differentiation in the actual curriculum.

It is obviously important and equally difficult to apportion accurately the influence of environment, tradition, and suggestion on the one hand, and hereditary and inborn tendencies on the other hand. The circumstances of women doctors and students of medicine, though infinitely better than sixty years ago when the struggle for any opportunities at all was in progress, are even now not so good as those of men; for example, the hospital facilities and appointments open to them are still restricted as compared with those of men. On the other hand it must be remembered that some of the best work done by men has been accomplished in the most unpromising surroundings; and it has been truly said, "genius does what it must, talent what it can."

Though much less than in the past, the sexes still lead different lives; girls are more prone than boys to follow an indoor and confined routine and so to impair or retard a robust physical development; and thus sexual peculiarities are accentuated. The physiological disabilities arising out of sex must be taken into very serious account as a weighty factor in determining women's chances of a successful struggle in intellectual work and practice of the profession of medicine. In 50 per cent. or more of women the monthly rhythm is a distinct handicap, and its manifestations are prone to be aggravated by a sedentary life and other factors prejudicial to a vigorous state of health, factors often inseparable from the life of a hard-worked doctor in town or institutional practice. For the greater part of their active life a large number of women are liable to recurrent interruptions in their state of efficiency and are thus at a grave disadvantage as compared with their male competitors; among men migraine, which might be regarded as comparable in its periodicity and effects, is relatively so rare that it rather tends to emphasize the reality of the women's burden.

Women have in a more developed degree than men the power of rapid perception or intuition, allied to second sight and clairvoyance, or of arriving at a correct solution of a problem *per saltum*. In his *In Defence of Women*, a book published in 1923 and in many respects Shavian in its daring, H. L. Mencken insists that so-called women's intuition is a high-grade form of keen intelligence which is rare in men and is then only found in men of special talent for the logical. Now this property—which is said never to have led to any discovery in science (Ludovici<sup>2</sup>), though both Darwin, who it is true silently spent twenty years in working it out, and A. Russel Wallace arrived at the conception of evolution by a flash—appears to be closely allied to imagination, which by providing possible explanations opens the road "to search and study out the secrets of nature by way of experiment." But apart from its potential use and application in research this faculty of arriving immediately at a correct opinion without the process of conscious ratiocination resembles the clinical instinct born of long years of experience and no doubt a function

of the unconscious, which is so invaluable in diagnosis and prognosis; hospital sisters often have this power, and when reinforced by a more extensive scientific training it should be an asset of women doctors.

The ability of women medical students has been abundantly shown by their distinctions in examinations. It may be interesting to compare the percentage of qualifications among men and women entering the medical profession. Sir James Paget's well known analysis in 1869 showed that of 1,000 medical students at St. Bartholomew's Hospital, 776, or 77.6 per cent., actually qualified; of Sir Squire Sprigge's smaller series of 250 students in the early eighties from St. George's Hospital, 187, or 75 per cent., qualified. Miss L. M. Brooks, your warden, has kindly analysed for me the results of 700 students entering the London School of Medicine for Women between October, 1894, and July, 1914; of this number, 593, or 84.7 per cent., completed the qualification for which they entered; this proportion is much the same as that (about 85 per cent.) arrived at by the General Medical Council in 1907, and that (87 per cent.) of the students entering St. Thomas's Hospital in the years 1890-1899 (Edred Corner). As far, therefore, as these few figures go, women students have held their own. It is satisfactory to learn that the death rate during pupillage, which in Sir James Paget's series was 4 per cent., was halved in Sprigge's and Corner's series and was little more than 1 per cent. (8 in 700) among the students of this school.

Though a high place in the class list provides a good start and is *prima facie* ground for anticipating success in after life, it is of course no guarantee for women students any more than it is for men. Although many prize winners continue to be front rankers, early success is not without its possible danger; it may breed conceit and slacken effort, so that the highly placed may become extinguished by their distinction. An early failure is sometimes a blessing, however much it may be disguised. Another consolation for those who fail to find favour with examiners is that some students develop late and so at first do not compete on equal terms with their more brilliant rivals, though eventually they surpass them in the race of life. To the make-up of a capable medical practitioner professional knowledge is not the only property necessary: practical efficiency, presence of mind, wise discretion, sympathy, and a thorough understanding of human nature are other essentials. Academic success may be obtained by mental ability, industry, and a temperamental power of making the best of knowledge thus acquired. Book knowledge may therefore go further in the examination room than in the daily round of practical life.

Women are on the average better students than their brethren, they work harder and take more pains, being more whole-mindedly concentrated on the subject in hand—so much so, indeed, that many of them find it difficult to throw off their work for a time and therefore tend to get stale and mentally dyspeptic. The power of detachment, by which mental concentration can be transferred from one thought-tight compartment to another, is of infinite value. Another aspect of detachment was so charmingly painted by the late H. D. Ellis (*Poems, Mathematical and Miscellaneous*, 1912) that it may be reproduced here, even if it be a little apart from this immediate context:

"Greatly prize the gift of humour,  
Light divine of human mind;  
Live unmoved by transient rumour,  
Harbour not a thought unkind.  
So will trouble, life's consumer,  
Break, like bubble in the wind."

But to resume, the importance of cultivating a hobby, distraction, or avocation to balance and correct the most urgent claims of professional studies is a commonplace yet like many dictates of common sense it is often ignored. Literature, music, art, and athletics are not only part of a liberal and humane education, but invaluable as a means of refreshment and of re-creating energy for the business of life. Just as there are burly athletes who never study, so are there pale students who go to the other extreme and thereby endanger their future by undermining both the mental and their physical efficiency. As a class women students are more prone than their brothers to over

MEDICAL, SURGICAL, OBSTETRICAL.

## UNITLATERAL GYNAECOMASTIA.

The following case is of interest on account of its comparative rarity, and because of its well marked features. I first noticed it during a medical inspection of one of His Majesty's vessels, and obtained a photograph and these particulars.

Age 23, single. He first noticed a swelling of his right breast in 1916—that is, when nearly 17 years old—and was told by a medical man that it was due to "pulling of the strings." The breast had changed slowly for eighteen months and has remained stationary since. There has never been any pain or discomfort in any way, and he has been subject to a certain amount of ridicule from his classmates. He voluntarily stated that the swelling seems to lessen some days the swelling seems to lessen. The breast consists of a uniform hypertrophy of about the size of an ordinary multiparous female breast. It moves freely, laterally, upwards and downwards over the pectoral muscle. The margins of the gland are well defined and it is uniformly firm in consistence. The nipple is a little larger than the corresponding one and is quite soft and moves freely. He has never noticed any discharge from the nipple, nor could I obtain any by pressure.

appear clinically to be quite normal and are not different from the other signs of feminization. There are feminized breasts but there is no enlargement of the thyroid, nor any history of enlargement or disease of that organ. The man is quite fit and able to carry out the strenuous life of a sailor.

It is impossible to obtain a familial record apart from the statement that his mother had a swelling in front of the neck in 1915, the last time he saw any of his family.

A. A. POWERS, M.B., Ch.B.,  
 Surgeon Lieutenant, R.N.

HAEMORRHAGIC DISEASE OF THE NEWLY BORN  
TREATED SUCCESSFULLY BY INJECTIONS  
OF THE FATHER'S BLOOD.

THE following case is, I think, of sufficient interest and

On Sunday, September 2nd, at 4.30 p.m., a patient was delivered

The infant was born at 2.30 p.m. on 22nd April 1964. The mother was a primipara, 26 years of age, with a previous pregnancy complicated by toxæmia, which lasted eight hours. The other three children (two girls, one boy) are in perfect health and have histories of "bleeders" in the family. The infant was born in normal labour and was perfectly normal. The placenta was delivered without undue delay, and the membranes were intact. Examination failed to reveal any abnormality. The infant was cold and clammy, and the umbilical cord was suppurative and the temperature was subnormal, and the rectal temperature was 35.5°C. The infant was asphyxiated to a lesser degree than the other children. In addition there was haemorrhage to the blood discharged from the bowel was dark-colored and free of mucus, and at the same time there was melæna. She was then vomiting bright red blood in 10-15 ml. quantities, and at 2.50 p.m. she was let at 2.50 p.m. There was haemorrhoid of "bleeders" in the family.

For twenty-four hours I had a 20 c.c. record syringe at my sleeping point in the mountain of meat. I immediately injected the father to let me take 20 c.c. of blood from the median basilic vein of his right arm, and I projected it subcutaneously in the right gluteal region of the patient. The continued sleep soundly until 10.30 p.m. and ceased at 11.00 p.m.

[illegible]

At 8.30 a.m. I found that there had been no further bleeding or bleeding from the vagina. There was still the slight melaena, without any faeces mixed with it. The infant continued to make satisfactory progress, with no visible haemorrhage. During the next week there was no further haemorrhage.

the forceps. If I could get Dr. McLeskie seriously to look at the preventive side of obstetrics I should be satisfied.

campuses, and very interested in his report on the use of x-ray photomicroscopy as a means of diagnosis. Dr. Johnson thought that my address was a very provocative one to the family doctor, and he remarked that he referred to "a current with them." I do not agree with this. I have a large number of friends in the medical profession, and have received from them many letters thanking me for the help and ideas I have given them in my writings and otherwise. Moreover, I have never

to give each the benefit of his experience. If he does not only to the medical profession but also to the public, he is placed in positions of trust it is his bounden duty, the specialists have a part to play. If we are to make progress in medicine and surgery, as a whole, is greater than that of individuals or of them, and that their knowledge will be realized only if they are fully aware of what they are doing. It is in fact, as I said at the beginning, that the physician must be able to understand more and more completely the nature of the disease which he is treating, and put himself in the position of the patient, so that he can see things from his point of view.

[illegible]

or labour. I should have thought that it was obvious from the context of my address that I did not advocate this as a general practice; my point was that two hours should not be regarded with the same respect as the "Ten Commandments." Neither did I say that all the forces commanders were of a major variety, but that the high forceps operation certainly was.

I thank the President for his kind remarks, and am glad that he takes up the idealistic view. Certainly I agree

that performance should be performed more often in preference to delivery with the forceps, in those cases in which undue force would have to be employed, for the rate of mortality and especially that of morbidity in the mother would be much lowered. Efficient ante-natal supervision, however, abolish the necessity for such an operation. I was very interested in the amusing and instructive remarks of Dr. Douglas. His description of his maternity work in Scotland was as near to my ideal as may be.

Eridently Scotland, as usual, in this respect as in others, is in advance of the general practice. Dr. Douglas gave an idealistic account of the work of general practitioners in obstetrics. He could not understand a man who did not use gloves and antiseptics in midwifery; neither can I, and yet I consider what percentage do. Dr. Groves thinks that an "aseptic hand" is better than Indian rubber gloves. If he will refer to the definition of aseptics and after this prepares his hands accordingly, he will pass

[illegible]

The last speaker attributed to me the remark that no force should be used in delivery with the obstetric forceps, which, as Duffell says, is absurd. What I did say was that no undue force should be used. Further, and by way of having much experience, he remarked that he had never failed to deliver with the forceps. I hope that God had mercy on his soul.

beneft of his patients and their offspring, that in the future he will in some cases fail in his well-meaning endeavours.

necessary to acquire the habit of noting down on the spot, or at least on the same day, the details of a case; yet this occupies little time, and this supplement to memory, or to adopt Addington Symonds's phrase this "mechanical memory," may in future emergencies—for example, legal proceedings, or certificates—be of the greatest use. In addition to writing a little every day some time should be given each day to reading, both of a professional and of a general kind, so as to keep up to date and maintain the general culture so essential to the medical practitioner, whose motto should be "Nihil humanum a me alienum puto." As an element in success accuracy and punctuality should not be overlooked; a present doyen of the profession when a young man on arriving at one of his first consultations was met by a senior surgical colleague standing watch in hand on the doorstep and the remark that a habit of being five minutes late boded badly for future success; this hint, gentle or otherwise, had a lasting effect and the resulting meticulous punctuality no doubt played some part in his triumphal career. A more difficult factor in avoiding failure is to be prepared for whatever emergencies or calls may occur in practice; this demands thoughtful foresight and some imagination. The whims of chance of course influence the future in ways that to some onlookers may seem even unfair, but probably many of the "lucky ones" are so in virtue of their ability to turn opportunities as they arise into solid advantages.

Though this address is headed "The Problem of Success for Medical Women," at this comparatively early stage of women's activity in the medical profession it is not wise, and indeed is hardly possible, to say the last word on this subject. That medical women have succeeded in the face of great difficulties is shown by recent history, and now that circumstances have been so vastly improved by the pioneers the road has been opened to their successors. The way, no doubt, is long and beset by difficulties; patience, perseverance, and wisdom are necessary though exacting requisites, but there is encouraging evidence that by these means women may look forward to a just meed of success.

## THE REGULATING AND REFLEX PROCESS.\*

BY

P. T. HERRING, M.D.,

PROFESSOR OF PHYSIOLOGY, ST. ANDREWS UNIVERSITY, AND  
PHYSIOLOGIST TO THE ST. ANDREWS INSTITUTE FOR  
CLINICAL RESEARCH.

## PART I.—THE ANATOMICAL AND PHYSIOLOGICAL UNITS.

THAT the early symptoms of disease manifest themselves by alterations in the normal reflexes of the body is a postulate laid down by Sir James Mackenzie. The truth or otherwise of this hypothesis is being investigated at the St. Andrews Institute for Clinical Research, but before any steps can be taken in its application to the study of abnormal conditions it is essential that a clear understanding be arrived at of what the normal reflex really signifies, and of the general principles which govern its production. Probably no branch of physiology has made greater progress in recent years than that relating to the nervous system. Many problems still await solution, but general principles are emerging which are of far-reaching importance.

A brief review of the general principles underlying reflex action is essayed in these articles, and an attempt is made to extend their application to the study of abnormal conditions. The author is conscious that some of his interpretations of ascertained facts are open to criticism, and may be modified in the course of time. There can be no finality in a subject of this importance, but a statement of the general position as it seems at present to members of the St. Andrews Institute may be of value.

\* The expense of this research was in part met by a contribution from the Medical Research Council.

## THE ANATOMICAL UNIT.

The anatomical unit of the nervous system is the neurone, which is the nerve cell with its processes, dendrites, and axis cylinder. Chains of such units make up the nervous system. The neurones do not blend with one another anatomically at their junctions but are separated by a minute interspace in which there is a material endowed with distinct and highly important properties. This is the synapse or "synaptic membrane."

## The Reflex.

It is improbable that any one anatomical unit in the nervous system can under normal conditions function by itself in the transmission of nerve impulses. For most purposes at least two neurones with an intervening synapse appear to be necessary to make up a functional unit. One of these neurones must be an afferent one whose province it is to transmit the nerve impulses excited in it by the stimulation of specialized end-organs or "receptors." The other neurone is an efferent one, and conducts the nerve impulses to some tissue or organ, which responds by whatever action characterizes it. Between the reacting organ or "effector" and the ending of the efferent neurone there is another minute interval occupied by a material somewhat similar in its properties to that of the synapse. Such an arrangement of anatomical units forms the basis of the simplest functional unit, which is the "reflex." An apparent exception to this statement is seen in the case of the so-called "axon reflex," where an afferent neurone sends branches to neighbouring arterioles and capillaries. But in the axon reflex the nerve impulses arise as usual at the receptors and pass to the central nervous system as well as to the blood vessels. The axon reflex appears to be a complete physiological unit in that a suitable stimulus applied to the skin produces a local vaso-dilatation of the blood vessels by the passage of nerve impulses over part of the afferent neurone only. But we do not know if this is the sole result of the stimulus, for the same neurone conducts the nerve impulses to the central nervous system, and sensation and reflex action may result in addition to the axon reflex. The axon reflex illustrates a principle of fundamental importance, because it shows that nerve impulses set up by a receptor in an afferent neurone may be productive of more than one kind of end-result. In general it may be said that the reflex is the physiological or functional unit, and that the reactions of the nervous system are built up of such units.

The modern view of the function of the neurone is that it conducts nerve impulses. It does so in response to stimulation, just as a muscle cell develops a state of tension in response to stimulation. But the nervous system is more than a highly elaborate conducting mechanism. The neurone conducts, but it manifests some degree of energy in doing so, though the amount of that energy is very small. There is no evidence that under normal conditions the nerve impulse dies down or undergoes a decrement in the neurone. The nerve impulse may be extinguished in the central nervous system, but such extinction always takes place at the junctions between the neurones—namely, in the synapses—and not in the neurone itself. On the other hand, nerve impulses set up in an afferent neurone may spread widely in the central nervous system, and the total sum of the resulting discharges by the efferent neurones may be greatly increased.

## Rhythmical Activity of the Neurone.

Single, unrepeatable nerve impulses do not, as such, find a passage through the central nervous system. In the quickest voluntary movement possible the muscular contraction is due to more than one nerve impulse, and there is evidence that the efferent neurones supplying voluntary muscle have a rhythm of discharge of about 50 per second. It is not known whether all neurones possess the property of rhythmical discharge, or what differences occur among them. It has been shown by Sherrington that if a stimulus applied to the afferent neurone in a reflex arc is sufficiently strong the efferent neurone has an after-discharge, and the muscle supplied by it remains in activity

The second point was never to advise operation for removal of a semimature cartilage which had once displaced and successfully reduced. Frequently the accident of recurrent trouble with a knee, which sounded superficially like a displaced cartilage, but in whom true locking of the joint had been absent. Mr. Ellis treated all these cases by manipulation, warning the patient that if the cartilage was damaged there might be a recurrence of the trouble necessitating operation. He believed that many of the so-called cartilage injuries cured by bonsetters came into this class, and that there had never been damage to the cartilage at all. Other cases so "cured" were those he had already mentioned in which the cartilage was displaced once and once only. In them the cartilage was presumably displaced by manipulation into a position where it gave no trouble. He did not believe that the bonsetters had any special manipulative tricks. If so, he ought to disclose them, just as any of the audience would put on record any new method which might be devised.

It was impossible to enumerate the many other conditions amenable to treatment by manipulation. They ranged from joints and muscles painful on account of apparently trivial restriction of movement, to gross cases of stiff joints, of adherent muscles, and nerves such as the sciatic which were affected after an old-standing neuritis. He would suggest that wherever there was possibility of improvement by well devised manipulation it should be tried. If the pathology was correct they could do no harm. Often they would cure the patient. How much improvement they could provide would depend on individual knowledge and experience. Whenever a joint or muscle was apparently normal, but yet was painful, manipulation should be tried. If diseases and mechanical effect had been eliminated no harm could result, and in nine cases out of ten some minor adhesions, undetectable by clinical examination, would be felt to give, and the patient would be cured. They failed to cure by manipulation most often because they failed to give the method a trial. Let them use it freely, restrained only by their knowledge of pathology.

## Pathology.

### SCIENTIFIC METHOD.

Let another book on scientific method, and this not a small one. However, the volume is to fill a place in a series; and many people who leave old works in their dust will read a new one. Moreover each writer has his own way of restoring old problems; and the fresh and bright, if somewhat dubious and discursive, style of Mr. Ritchie's volume, pleasant book for the general reader. Taken as a whole Mr. Ritchie's *Scientific Method* is able, comprehensive and, in our opinion, right in its main argument and conclusions; if in friendly controversy we might be tempted to challenge some parts of it we are compelled by reason of our space to resist the temptation.

After an introductory chapter, Mr. Ritchie divides his subject into the following sections: The External World, Natural Laws, The Validity of Laws, Measurement, Theories, Conclusions. Some such artificial divisions must, of course, be made, but they entail overlapping, repetitions, and divorces of thought; so that it is less easy to get a grip on the book as a whole. And the style is hardly tight enough. In a second edition more might be done to whip the matter together and condense it; and some mechanical aids—such as indents or subheads—might help the author to concentration, and the reader to comprehensions. The problem of the formulation of our knowledge, of the establishment of principles on which forecasts may be founded, has occupied the mind of man ever since he began to think at all. As Mr. Shann says, in his excellent little book on *The Evolution of Knowledge*, the need of forecasting is as old as the hills.

*Scientific Method. An Inquiry Into the Character and Validity of Natural Laws.* By A. D. Ritchie. The International Library of Psychology and Scientific Method. London: Hegan Paul, Trench, Trubner and Co. 1933. (Pp. 699. 10s. 6d. net.)

casting the consequences of voluntary action drove even the faculties may have arisen at an early stage of evolution. The empiric is not without principles, but he likes them familiar and traditional, even if out of repair. For ordinary argument, the presumption of a world external to sense must be accepted; even if it be but a convenience of thought. So again, as a thing can be known only as it changes, and as with it all other things change (as an ancient sage well said)—to abstract any single item from the cosmos would be to alter the whole, to isolate it for analysis is a "species present" can be but a convention. As we take all knowledge to be for use, immediate or ultimate, as for forecasting, so every new abstraction must from time to time be reified with its proper content, that it may be verified and reclaimed. If theory and experience fall out of agreement the theory has been so far incomplete.

Are not scientists a little too chary of philosophy—that is, of the study of principles? If the scientists is to know where he stands—to be Plato's *στωικός*—he cannot altogether ignore the lead of philosophy, nor its criticism of the natural sciences. As Mr. Ritchie says, outside physical science little colonies of knowledge are to be found; some flourishing, some languishing. To propose to understand a whole without analyzing it by parts would be a formidable job. Yet it is only by conventions that we can clearly distinguish between the principles of continuous natural growth and our methods of obtaining a knowledge of them; between that is, experience and thought. What constitutes evidence? How far is a universal a key, or a mere negation of individual properties? The scientist must assume a correspondence between the perceptible universes and the patterns of our brains; but is there anything more than this, any vital blind of consciousness—of inner light—with the object? Was there anything in the Xous of Anaxagoras, or in medieval dualism, or in Maxwell's "sorting demon," or in a phrase—What does the mind supply, and what is given to it? As Mr. Ritchie and Mr. Shann impress upon us, we scientists still are not unaffected by the error of Francis Bacon, who supposed that by a ladder of axioms any industrious observer could climb up to general laws. The Aristotle of his day was, of course, an imperfect and often false parasite. Many scientists are now beginning to realize that a kind of imagination, different seemingly from the creative or concrete, some genius for hypothesis, is essential to the research. But, as men of this larger reason are rare, may it not be better to strengthen the position of the few than the inability to multiply studentship; and to be careful not to superannuate men so endowed at ages of maturity? The faculties of the fine (creative) arts bloom much earlier than those of scientific range.

We are too ready to scoff at the "unbridled and windy speculations" of the great Ionian sages, counting their hypotheses with medieval dialectic. The frailty of their great conceptions lay not in the concepts themselves—these were indeed marvellous forecasts of those of modern evolutionists—but in their lack of building materials. Hippocrates in medicine, and Aristotle in animated nature began their collections of materials to which later workers have added so rashly that, fed by them, stouter and stouter superstructures have been built. As life from chaos, so theories have grown upon the sod of defunct hypotheses. In the recent divorce of science from letters science has torn away trappings which hindered its course; but it has lost much of value; it has lost continuity, and precision of terms and words. What would become of a mathematician, or of a logician, who used ambiguous signs and terms in his demonstrations? Yet scientific writing is full of such laxities; some of them, we regret to say, Mr. Ritchie does not indeed defend, but accepts in order to settle up with the man in the street. For instance, a theory is the highest form of scientific truth; there is no other word for it; yet by too many persons "theory" is used indifferently for any assumption or opinion. Again, a "fact" is something that has happened—an event—whether we know it or not; and by itself, out of relation to other facts, it is nothing. To call

sensation are identical with those which are concerned on the afferent side with the production of Pavlov's "conditioned" reflex. The difference between the sensation and the reflex really lies in the nature of the process which produces the end-results. A sensation is a physiological or functional unit of the nervous system just as a reflex is, and if the part of the brain which is responsible for the processes underlying consciousness be regarded as an effector the sensation becomes a reflex. From the clinical standpoint the sensation is as important as the reflex, and the causes which produce disturbance in the one may produce disturbance in the other, and the manner of production of the disturbance is in large part the same in both. The term "reflex," though a very elastic one, has a definite meaning, and there are difficulties in classifying sensation under it. A new term for the physiological or functional unit of the nervous system which would embrace sensation, reflex, and voluntary movement might be better. It is this physiological or functional unit of the nervous system which is affected and gives rise to the early manifestations of ill health.

#### Voluntary Movement.

The cerebral cortex gives origin to the impulses which bring about the contraction of voluntary muscle. The dendrites and bodies of the neurones concerned, the cells of Betz, which constitute the first neurones of the efferent chain, lie in the precentral convolution of the frontal lobe. There is no reason to suppose that the cells of Betz are automatic; they must be set into activity by nerve impulses reaching them from some other neurone. In the production of voluntary movement the nerve impulses pass from the cortex by the first efferent neurone into the lower level of the central nervous system, where they then make use of the efferent pathways of the lower or spinal reflex mechanism. The cells of Betz may be looked upon as part of a long reflex arc the efferent part of which begins in the cerebral cortex and extends to the lower level of the central nervous system. The cells of Betz may be set into activity by nerve impulses which reach them through the long afferent paths involved in the production of sensations. This form of activity may become a reflex taking place through the cerebral cortex, and is comparable with Pavlov's "conditioned" reflex, though its end-result is seen in voluntary muscle. Many of the complex movements make use of these long pathways. Speech, reading aloud, writing to dictation, the playing of musical instruments, and skilled movements generally, afford examples of voluntary action which have many of the characteristics of reflexes. Initiated voluntarily by some unknown process involving cerebral activity they may lose their voluntary character, and when the pathways for the nerve impulses have been cultivated by use the process becomes a reflex one. Some of the responses may be continued by a short-circuiting as it were from the afferent to the efferent side at intermediate or lower levels. But in man the provision for even the simpler reflexes tends to be promoted to the higher levels. In injuries to the human spinal cord involving complete severance from the higher levels the part of the cord below the lesion fails at first to act as a reflex centre and only recovers as such when the direct pathways from the afferent to the efferent side in it have been re-educated.

#### Reciprocal Innervation.

The contraction of one muscle or of one group of muscles cannot take place without affecting the state of other muscles. When the muscles which produce flexion at a joint are contracted the muscles which oppose the movement, the extensors, are stretched. In a reflex or voluntary contraction of muscles, exciting a definite act such as flexion, provision is made in the central nervous system for a twofold action. The stimulus which excites the discharge of nerve impulses by the efferent neurones supplying the flexor muscles also inhibits the activity of the efferent neurones supplying the opposing extensor muscles. There is indeed an actual elongation of the opposing muscles due to their sudden loss of tone. A reflex or voluntary contraction of one group of muscles is not a complete manifestation of the end-results of the nervous process concerned, for the nervous system is so arranged

that muscle has a reciprocal innervation. The phenomena of reciprocal innervation, the contraction of one group of muscles and the relaxation of another group, may be occasioned by nerve impulses coming from the higher levels as in voluntary movement, or by impulses entering the lower level of the central nervous system by afferent neurones from the periphery as in reflex movement.

Changes in the tension of each muscle excite receptors—the muscle spindles—in the muscle, and afferent nerve impulses are carried to the central nervous system, where they are co-ordinated and distributed to efferent neurones, stimulating some and inhibiting others, and thus leading to alterations in the tone of the muscles supplied.

The contraction of muscle alters the relative position of the parts of the body to one another. A constant stream of nerve impulses is carried into the central nervous system by afferent neurones from the proprioceptors, the receptors which are acted on by gravity and movement—for example, the utricle, saccule, and semicircular canals—and the receptors acted upon by tension—for example, the muscle spindles, and nerve endings in joints, ligaments, and other structures. Many of these impulses appear to be directed into the cerebellum, which Sherrington terms the head ganglion of the proprioceptive system. The impulses are co-ordinated in the cerebellum and distributed from it to efferent neurones in the lower level of the nervous system, and lead to alterations in the postural tone of the skeletal muscle.

The contraction of muscle, whether voluntary or reflex, is not an isolated act, but is accompanied by numerous complicated events in the central nervous system. The changes in muscle tone brought about by reflex action are of far-reaching importance, but are as yet imperfectly understood. Evidence is accumulating that the nervous processes concerned in the production of tone are in some respects different from those that have to do with ordinary contraction. The metabolism appears to be of a different character in the two events, and it is possible that the autonomic system plays a part in the maintenance of tone and of continued or tonic contraction of voluntary muscle, and that the actual contraction in the muscle is of a different nature.

Reciprocal innervation is not confined to voluntary muscle, but occurs in the innervation of all forms of muscle, and is shown by the heart and by the blood vessels. There is a close correlation of these organs by the nervous system. The contraction of voluntary muscle involves changes in the rate of the heart, the distribution of blood in the blood vessels, and alterations in metabolism. The liver liberates more glucose from its glycogen, and a number of changes take place in the chemistry of the body. The body is a unit and all parts work together. No change can occur in any of its parts without the production of some effect upon the others and upon the unit as a whole. If one examines the ascending columns of white matter in the lower level of the central nervous system one cannot but remark upon the great preponderance of neurones which are not associated with sensation, and which must be concerned in the production of reflexes. The central nervous system must be in constant receipt of afferent nerve impulses from all parts of the body, many of which have no direct representation in consciousness. Alterations in these impulses bring about changes in the body of a reflex nature. The altered reflex may in turn have a secondary effect upon consciousness. Reflexes involving alterations in metabolism, in the rate of the heart, in the distribution of the blood, and in respiration, to mention only the more obvious reflexes, may excite changes in consciousness which give knowledge to the individual that all is not well, though the nature of the sensation is vague and its actual cause is not recognized.

#### Health and Ill Health.

In the St. Andrews Institute we assume that health consists in the harmonious working together of all the organs and tissues of the body. The process by which this is effected is a nervous one of great complexity. A state of health implies that all parts of the body are furnishing from the various receptors their normal quota of afferent

method is nearly perfect and in his skilled hands has achieved the success which he claims. Nevertheless it is not a procedure likely to be of general application for this common complaint, and it is not difficult to imagine disastrous results, should this advice mislead the inexperienced. The indications for operations, as expounded by Dr. Barnes, are too rigid and there is a failure "to make the punishment fit the crime." In the chapter on complications and sequelae of operations on the tonsils an interesting account of pulmonary abscess following tonsillectomy is given. This complication appears to be commoner in America than in this country, but fortunately it is everywhere so rare that reliable statistics can scarcely be obtained. The effects of treatment of enlarged tonsils by x rays and radium is fairly discussed; it would appear from the general results that these methods are unlikely to have a wide field of utility.

The work of Dr. Greenfield Sluder is frankly a plea for the use of the guillotine in the removal of tonsils. He has, however, produced a complete work on the tonsils ranging from their embryology to their surgery. The most important part of the book is the detailed description of the operation and all that appertains to it. The author strongly recommends the use of nitrous oxide as the anaesthetic. He states that there has been no case of pulmonary abscess in his practice and that only one case of pneumonia has occurred in a series of 20,000 operations. It appears from the statistics that the use of a suction apparatus is an important factor in the prevention of pulmonary abscess. A fascinating part of the book deals with the evolution of the guillotine; it begins with the utrumlocom of Canute of Thorbern, a Norwegian peasant; the illustration suggests a thumbscrew rather than a surgical instrument. This historical part is profusely illustrated with figures of guillotine are represented, indicating that the operation presents difficulties which many have endeavoured to overcome by altering the design of the instrument. The instructions for performing the operations are given in most minute detail, and the artist has produced drawings which support and illustrate very well the points elaborated in the text; he is to be congratulated on his success, for the operation does not lend itself at all easily to graphic representation and has baffled many. A chapter is devoted to the removal of adenoids, and the author recommends an instrument which makes it possible to do the operation under direct vision.

The general style and appearance of both these books is excellent and they should be studied carefully by everyone taking any serious interest in laryngology.

### CRIME AND INSANITY.

Dr. WILLIAM A. WHITE, the well known American psychiatrist, has written a volume on *Insanity and the Criminal Law* in which he discusses the possibility of applying modern psychiatric principles in dealing with crime. Writing from the standpoint of analytical psychology he shows how the concepts of crime and criminal have grown out of a consideration of acts rather than a consideration of the actors, and he welcomes the increasing tendency to take into account the personality of the criminal in relation to the crime he has committed. The theory of the treatment of crime which Dr. White develops resolves itself into two parts. First, to do away as far as possible with the conditions (mental defectsiveness, insanity, immoral social conditions, etc.) out of which crime grows; and secondly, the salvaging of the criminal for social usefulness. He considers that the criminal in the majority of instances may be regarded as having a certain percentage of social value, and that it is therefore the function of the State to try to make that amount of energy available as a social asset rather than to allow it to be wasted in socially destructive activities. The author regards crime as a social disease and his main contention is that it should

### THE COMING GENERATION.

The *Claims of the Coming Generation* is a volume of essays by well known writers, based on the proceedings at the recent annual conference of the National Birth Rate Commission, and arranged by Sir James Merchant. There is nothing very new in the essays, which represent the views of many earnest thinkers on social improvement. It may be of some interest, however, to trace the principles which run through this series of essays. In the last place the title of the volume suggests the existence of "rights" for all human beings, and Dean Inge opens the symposium with an essay on the "Right to be well born." The Dean of St. Paul's holds that, "every child has the right to be well born." Therefore he makes an appeal to the medical profession to use "their collective authority in educating and influencing public opinion." Dean Inge draws up a list of subjects for an official handbook to be issued by the profession; in this list he includes the laws of heredity, the inherited tendency to certain diseases and moral defects, racial poisons, the stigmata of degeneracy, favourable age for marriage, effects of race mixture, the question of compulsory healthy certificates before marriage, and the best interval between births. Never mind, says the Dean, if half these questions cannot be answered with any certainty; let us hear the evidence, and so be gradually educated up to initiating legislation against obviously degenerative tendencies. The contemplation of legislation has the merit of interfering with the imposition of "duties" on some portion, at all events, of the community; but in this age, when rights are generally emphasized so much more strongly than duties, it might have been well to call attention to the latter in the title of the book and of the Dean's essay.

Not all the contributors are eugenicists. Thus Sir Arthur Newsholme prefaces his observations by the statement that "failures in parental care are the exception, not the rule," and by the further statement that—omitting the case of a few well defined diseases of somewhat rare incidence—"the efforts of eugenicists to influence family alliances have insignificant scientific basis for the making of practical recommendations." Nevertheless the eugenic idea runs through many of the essays, as

be treated as such, as the following quotations show: "Criminology, taking its cue from medicine, aims at preventing principles, or, in lieu of that, the next best thing the social rehabilitation of the criminal. . . . The situation is analogous to the relation between physician and patient only that here the disease is not individual but social and the place of the physician is taken by the State." Dr. White devotes much attention to what he regards as serious defects in the legal machinery for dealing with those cases in which a plea of insanity is raised in criminal trials. He discusses more especially the question of expert testimony, and expresses himself as convinced that the present procedure, in which the medical witness is treated as a partisan, makes it practically impossible for the expert to present a scientific position from the witness-box. He favours the suggestion, made by the American Institute of Criminal Law, that the judge may call in non-partisan experts to testify at the trial, and that these experts may be permitted to read a written report. As the author observes, this method of presenting the evidence to the court permits the criminal act to be described in its proper setting, to be given its proper value in a general behaviouristic survey of the personality, so that the real nature of the problem which confronts the court in the person of the defendant can be adequately presented. Dr. White's large experience enables him to describe a number of instances in which the plea of insanity has been raised in criminal trials, and his discussions of these cases are full of interest. We can recommend this book to all those who are interested in the problem of the criminal.

• *The Claims of the Coming Generation*: A consideration by various writers arranged by Sir James Merchant, K.B.E., LL.D., London: Regan Paul, Trench, Trubner and Co., Ltd. 1923. (Cr. 8vo, pp. 175, 6s. 6d. net.)

• *Insanity and the Criminal Law*. By William A. White, M.D., New York: The Macmillan Co. 1923. (Cr. 8vo, pp. 231, 12s. 6d. net.)

necessity of the division of the sac, as may occur in rare cases. The history of the case, the presence of a "palpable, definite, resonant mass, slightly movable, but not on respiration, and gurgling on auscultation," with retraction of the region corresponding to the colon, would permit a probable diagnosis to be made. No coils of intestine were visible.

As pointed out by Moynihan and Dobson, the plica venosa forms the upper anterior and lower boundaries of the orifice of the sac. This fold contains the inferior mesenteric vein, but in this case there was no obvious implication of the haemorrhoidal veins, nor was any collateral circulation developed in the abdominal wall.

It will be noted that the patient ascribed her condition to an accident. According to Treitz, duodenal herniae are always acquired, being caused by a violent effort, such as a blow, shock, or concussion. Landzert, on the other hand, states that these herniae are always congenital. Moynihan and Dobson state that all the essentials for the development of hernia are present in intrauterine life, and that the hernia is chronic, whether congenital or acquired, the strangulation alone being acute. Cases have been recorded as early as the ages of 14 days and 3 months.

No attempt was made to suture the hernial opening owing to the condition of the patient. This procedure involves two risks: one is that of injury to the mesenteric vessel, and the other the formation of a large peritoneal cyst.

### III.—INTESTINAL OBSTRUCTION FROM GALL STONES.

In the following case delay in operation was due to the difficulty of diagnosis, or rather perhaps to the failure to recognize the condition. The onset was one of overwhelming violence. The patient was extremely obese. There was also a curious intermission in the symptoms, in which pain and vomiting ceased and flatus was passed. The latter was probably due to reversed peristalsis, making the calculus slip backwards, and thus removing the obstruction.

Gall stones most frequently cause obstruction by impaction, but they may also cause obstruction indirectly by producing volvulus, and by their pressure they may cause ulceration of the gut and subsequent stricture. Obstruction from gall stones may occur anywhere from the pylorus to the anus.

Mrs. M., aged 55, admitted August, 1921. Two or three days before admission she had an attack of violent abdominal pain, accompanied by vomiting and the cessation of the passage of flatus. On admission the vomiting had ceased and flatus was being passed, and this caused further delay in operating. The symptoms of obstruction recurred, and operation was performed. The gall bladder was thickened and shrunken, and a gall stone the size of a large walnut was found impacted in the lower ileum. This was removed, and distended coils of intestine were emptied at the poisonous proteose level of Wilkie. The patient did not recover.

### IV.—INTESTINAL OBSTRUCTION FROM UTERINE FIBROID.

An unusual cause of acute intestinal obstruction is a fibroid tumour of the uterus. According to Bland-Sutton, uterine fibroids may obstruct the intestine in three ways:

1. A pedunculated subserous fibroid may entangle a loop of small intestine and lead to fatal obstruction.
2. A very large fibroid may rest on the brim of the pelvis, thus obstructing the sigmoid flexure.
3. An impacted tumour may press upon the rectum, and lead to obstinate constipation and chronic obstruction.

The following is an example of the second variety:

Miss B., aged 50, admitted to hospital May 10th, 1921. The day before admission severe pain set in in the abdomen. Vomiting was persistent and continuous. On admission a huge myoma occupied the pelvis and well filled the abdominal cavity. Operation was at once performed. No bands or adhesions were present. Access to the broad ligaments was very difficult. The bladder, therefore, was detached from the anterior wall of the uterus, and the cervix was divided by passing a scalpel from the anterior to the posterior surface in the middle line, and cutting outwards toward the uterine arteries. It was not very difficult then to divide the broad ligaments from below upwards, thus rapidly removing the uterus with its appendages. Recovery was rapid and complete.

### V.—INTESTINAL OBSTRUCTION FROM HERNIAE.

Cases of intestinal obstruction from inguinal or femoral herniae, if the patient is feeble or in *extremis*, may be treated as follows:

Using Gray's syringe, infiltrate the skin and subjacent tissues with novocain 1/2 per cent. Incise the skin, open the sac; if the bowel is gangrenous incise it also, but if in good condition dilate the constricting structure with the index finger, and return the hernia or not, as seems advisable. Incision from within is unnecessary in dealing with the constricting ring in any strangulated hernia. Digital stretching is sufficient and safer.

The stethoscope is of much value in the diagnosis of various abdominal conditions, and in intestinal obstruction it is not difficult to recognize the passage of intestinal contents through wide or narrowed parts of the bowel.

The chief points in the diagnosis of acute intestinal obstruction are: (1) continuous and persistent vomiting; (2) no passage of flatus in twenty-four hours, notwithstanding appropriate treatment; (3) increasing abdominal distension. We must not wait for the onset of so-called faecal vomiting. It is a sure sign of intestinal obstruction, but it is also a clear indication that death is imminent.

### A CASE OF ANGIOCHORIOMA.

BY

O. J. REID, M.B., B.Ch.N.Z.,

LATE RESIDENT MEDICAL OFFICER, CITY OF LONDON MATERNITY HOSPITAL;

AND

A. NEAVE KINGSBURY, M.B., B.S.,

B.Sc.LOND., D.P.H.,

PATHOLOGIST, CITY OF LONDON MATERNITY HOSPITAL; ASSISTANT  
PATHOLOGIST, MIDDLESEX HOSPITAL.

PLACENTAL tumours of the angiochoriomatous type are so rare that the following case, which occurred in the district practice of the City of London Maternity Hospital early this year, appears of sufficient interest to merit report.

The tumour which we now know as an angiochorioma was first described by Virchow as "myxoma fibrosus placentae," and since his publication only a few score cases have been recorded, the majority of these being from maternity hospitals where careful note is being kept of any abnormality. It may, therefore, be a somewhat commoner condition than the records would indicate.

These tumours arise from the chorion, probably very early in pregnancy, and their localized condition has been held to mitigate the possibility of a maternal cause. Some writers have, however, suggested an inflammatory origin and syphilis has been incriminated as an etiological factor, without much weight of supporting evidence. An interesting explanation of their causation was offered in a paper read before the Annual Meeting of the British Medical Association in 1912, by R. W. Johnstone,<sup>1</sup> who suggested that obstruction to venous return from an area of the placenta might bring about the angiomatous condition.

Apart from the area invaded by the tumour, the placenta is usually quite healthy and functions normally. Hydramnios may coexist and the foetal mortality does not exceed 0.30 per cent.

#### Clinical History.

The patient was a multipara, aged 42. The pregnancy was normal except for an unusual degree of pallor, and during the pregnancy a painful "thickening" behind the left knee was noticed. She was delivered of a healthy full-term child. During the third stage of labour there was a free loss of blood, but insufficient to be termed a post-partum haemorrhage. Examination of the placenta showed the presence of a tumour. Five days after labour phlebitis and thrombosis of the left popliteal vein occurred: the temperature was 101° F. and the patient complained of a persistent right hemicranial headache. The uterus was well involuted. The heart was slightly dilated and haemic murmurs were noted. The blood pressure was 98 mm. No albumin was present. A blood count gave the following result: albumin was present. A blood count gave the following result: red cells 3,100,000 per c.mm.; haemoglobin 42 per cent.; leucocytes 13,100 per c.mm.; differential count: polymorphs 81 per cent., lymphocytes 15 per cent., large mononuclears 4 per cent.

THOMAS WAKLEY AND THE "LANCET."

The mysterious outrage in Argyl Street which interrupted the course and very nearly ended the life of Thomas Wakley more than a hundred years ago was as remarkable as was the subsequent career of that vivacious journalist and politician.

In his *Life and Times of Thomas Wakley*, the present editor of the *Lancet*, Sir Squire Spriggs, has admirably chronicled that career. Thomas Wakley was an impulsive, generous-hearted man who furiously resented the abuses and the injustice which were then rife in the medical profession. Inspired to a great extent by Cobbett, he and his assistants did not hesitate to attack in unmeasured terms the very heads of the profession. He seems positively to have revelled in controversy, and, far from thin-skinned himself, it does not seem to have occurred to him that any of his opponents might be more sensitive than himself, or when an appeal to the arbitrament of the pistol or even of the fist is no longer tolerated. Dickens probably did not greatly exaggerate when he described the *Katanswill* editors, Mr. Port denounced had had his forefinger in the "Hole-and-Corner Surgery," which fanned the life of the *Lancet*. We have come across the record of only one medical duel in this period, that between Dr. Forbes of the Westminster Ophthalmic Hospital and Mr. Thompson. The cause of quarrel was a dispute between Guthrie and Forbes as to the management of the hospital. Thompson warmly espoused Guthrie's cause and challenged Forbes. They met on Clapham Common. Neither of the principals seems to have been much of a marksman, for after three exchanges of shots without any casualty the seconds intervened, because, as they reported, "they could not, consistently with their own characters, permit the affair to proceed any further, however much they might regret that a reconciliation had not been effected." The seconds were probably more disappointed with the negative result of the duel than were the principals, and they seem to have thought that a bullet wound would have had a conciliatory effect.

A perusal of the early volumes of the *Lancet* will repay the student of the history of medicine and of the humours of journalism. One of the objects of the paper was the publication of lectures delivered by hospital surgeons and physicians, and it very soon began to turn the greatest of these, Sir Astley Paston Cooper. Sir Astley enforced his opinions with illustrations from his wide experience, as, for instance, when he told his hearers how a St. Thomas's dresser persuaded the surgeon to allow him to amputate his leg, and how the operator lost his head when the tourniquet gave way, and but for the intervention of a cooler-headed friend with a door key the unfortunate patient would have bled to death. Another extraordinary case which he described at length was one in which an artist sought relief from the deformity of "bow-shins," and the surgeon, the patient, and the patient's father took turns at scraping away the bone with a "rongeur." Unfortunately the granulations produced much new bone and the deformity became worse than ever. Then the surgeon, not to be beaten, applied arsenic freely. The result was excitation of bone and arsenical paralysis. After recovering from this, the patient sought Sir Astley's advice and showed him "a large box in which he had gone through. The reader of the present day cannot fail to be struck by the fortitude of patients who submitted

while the remaining chapters are devoted to the consideration of individual diseases or groups of diseases caused by micro-organisms as well as infectious disorders of unknown aetiology, including tropical and venereal medicine. A bibliography of almost entirely German authorities is appended to each lecture. Although the greater part of the work is taken up by bacteriological considerations it is not intended for bacteriologists exclusively, for in addition to a short account of the epidemiology and prophylaxis of the various infectious diseases as well as serum and vaccine therapy. The paper and printing are excellent, and there are numerous beautiful half-tone and coloured plates and microphotographs.

One of the most pleasing forms of introduction to the study of chemistry is that in which well known substances and familiar events are reviewed in a scientific light, and their properties and transformations described in terms conveying the ideas first impressed on the founders of chemical science. Such a book is that of KINGZETT, now in its fourth edition. "Illustrations and diagrams necessary for the understanding of manufacturing processes are provided. It may, in fact, be described as a book of pictorial chemistry containing more information than could be set down in the same area of letterpress.

*The Ventilation of Public Buildings*, by ROBERT BOYLE, contains a number of plans of public buildings illustrating the author's method of "natural ventilation." It dispenses with artificial contrivances for forcing currents of air through the building and depends solely on the natural upward currents which are present in the tower and inlets of proportionate size provided in the lower parts of the building. The text consists almost entirely of questions from the opinions of scientific writers, of newspapers, and of extracts from reports of Government and other committees, in praise of the system.

*Aspic Clinical Thermometer Case.*  
Circular thermometers are known which are adapted to contain disinfectants, so that each time a thermometer is inserted into its case it is dipped into the disinfectant. In order to avoid repeated use of the same disinfectant, while at the same time facilitating the carriage of disinfectant with the thermometer case so that it is always ready to hand, Dr. Charles Penland has devised a thermometer case with two compartments, one is for the thermometer and the other is fitted with a glass tube in which potassium permanganate crystals or any other suitable solid disinfectant may be stored. This tube has a small hole at the lower end; a few crystals of disinfectant are shaken into a glass of water allows the thermometer to be disinfected by the bedside of the patient. Dr. Penland has had a case in use now for nearly twelve months, and finds it acts perfectly. The appliance is made by Messrs. Arnold, Sons, Bell and Croyden, 30, Wigmore Street, W.

*Bomb Filter Apparatus.*  
Drs. S. R. Watson and K. B. Pirkson (Manchester) write: The bomb apparatus illustrated was first described in February, 1921, and has been in constant use ever since. We have, however, made additions and improvements in it. The valve illustrated has been made a great deal better. The nut, it is to be seen, is to adjust the action becomes loose, and it is to adjust the pointer; the filter plug is the top, and incorporates a device which prevents over-filling. A safety blow-off has been added, which makes the apparatus absolutely safe in all circumstances. A hand rest also has been fitted which adds to the convenience of the user when manipulating the valve. The apparatus has been in use for the last six years; indeed, we think it the easiest and most efficient way of manipulating ether. It is now manufactured by the Manchester Machine and Instrument Manufacturing Co., Ltd., 2, Booth Street, Manchester.

occurring in women: (1) well marked haemophilia resembling that in the male, (2) haemorrhagic diathesis in females not connected with haemophilic families, and (3) "an abnormal tendency to bleed in female members of admitted haemophilic families, such tendency being slight or atypical as compared with well marked haemophilia." The patient appears to belong to this last class.

I wish to thank Mr. R. H. Jocelyn Swan for his permission to publish this case; and Dr. Meadows of Yarmouth and the Registrars of St. Mary's Hospital, Paddington, the Victoria Infirmary, Newcastle, and the Yarmouth Hospital, for their kindness in supplying particulars of the cases under their care.

### INSULIN TREATMENT: A SUGGESTION FOR AN OPTICAL METHOD.

BY

W. F. LLOYD, B.A., M.B.,

PHYSICIAN, KING EDWARD VII HOSPITAL, WINDSOR.

The insulin treatment of diabetes requires an accurate estimation of the glucose in the blood, and an easy method by which this could be accomplished would be welcomed by general practitioners.

I have made determinations of the amount of glucose in solution by measuring the index of refraction of the solution. The instrument I have used is described in Schuster and Lee's *Exercises in Practical Physics*, and depends on the measurement of the critical angle. The instrument is simple, and only one or two drops of the liquid are required. It would have to be assumed that any alteration in the index of refraction of the blood was due to the amount of glucose contained in the blood, and in

a diabetic patient I think that this assumption warranted.

Starting with a 10 per cent. solution of glucose the index of refraction was measured, and weaker solutions were taken with the following results:

|    | 10 per cent. glucose | ... | ... | ... | Index of Refraction. |
|----|----------------------|-----|-----|-----|----------------------|
| 5  | "                    | "   | "   | "   | 1.341                |
| 2½ | "                    | "   | "   | "   | 1.338                |
| 1½ | "                    | "   | "   | "   | 1.336                |
| 1  | "                    | "   | "   | "   | 1.334                |

At about 1 per cent., therefore, the solution could be distinguished from water, which has an index of refraction of 1.333. The instrument, however, might be improved to give more accurate readings, and if this can be accomplished a quick and ready method of estimating the glucose is quite possible.

Another method which was attempted was a measurement of the rotation of the plane of polarization, but the same difficulty was experienced—the method was inaccurate for very small percentages.

Some years ago I made experiments on the index of refraction of the fluids of the human body with a view to distinguishing between inflammatory and serous effusions. The following table embodies my results:

|                      | Index of Refraction. |
|----------------------|----------------------|
| Pleural effusion     | 1.343                |
| "                    | 1.347                |
| "                    | 1.346                |
| Ascitic fluid        | 1.336                |
| Fluid from oedema    | 1.336                |
| Cerebro-spinal fluid | 1.339                |

I am of opinion that an optical method for determining the amount of glucose present in fluids can be elaborated which would give a more accurate result than the chemical method, would be more simple, and take much less time.

#### PROCEEDINGS OF SECTIONS AT THE ANNUAL MEETING, 1923.

#### SECTION OF OBSTETRICS AND GYNAECOLOGY.

VICTOR BONNEY, M.S., M.D., F.R.C.S., President.

#### DISCUSSION ON THE USE AND ABUSE OF OBSTETRIC FORCEPS.

##### OPENING PAPERS.

I.—COMYNS BERKELEY, M.A., M.D., M.Ch. Cantab., F.R.C.P. Lond.

##### EFFICIENT TEACHING.

I THINK it must be admitted that the very unsatisfactory position of the forceps operation to-day is due to inefficient teaching. It is not fair, as has often been done in the past, to shift all the blame on to the family doctor, and I feel that the teachers of obstetrics must shoulder their share of this responsibility, which, if anything, is greater than that of their pupils. That the teachers themselves are, however, not entirely at fault is obvious, for they have not the facilities to teach midwifery properly. In the end the responsibility for this inefficient teaching, in the past at any rate, must rest on the General Medical Council and the various examining bodies, who have it in their power to prescribe what rules and regulations they think fit.

The majority of students when they get into practice are not going to operate, and yet, before they can sit for their final examination, they have to spend three months in the out-patient and six months in the in-patient surgical departments of their hospital, working under the direct supervision of the chiefs of these departments. The majority of students, however, are going to practise midwifery, and yet many of the examining bodies do not

compel them to attend any midwifery cases in a hospital and there is no rule that any of the twenty women that must deliver shall be delivered under the immediate supervision of the chief of the department. Not many years ago the obstetric house-surgeon used to take the pupil to first two cases only, and he had to look after the remaining eighteen as best he could. Until lately it could be said without exaggeration that most men went into practice without ever having seen a woman delivered as she should be—that is, in suitable surroundings.

The life or health of a patient may easily depend on the good or bad judgement of the medical attendant, and often does. In no instance, perhaps, is this fact more striking than in the practice of midwifery. It is recognized that the only way in which students can attain good judgement is by being given efficient teaching and ample opportunity in practical work, but whereas both efficient teaching and ample opportunity are always within the reach of every student when he is studying medicine and surgery, when he comes to study midwifery his opportunities for practical work under supervision are extremely limited. Although it is now the custom, at those hospitals which have maternity beds, for the midwifery pupils to take their first two cases under the supervision of the obstetric house-surgeon or sister midwife, I believe, up to the present, only a few of the examining bodies insist on this. Apart from unavoidable complications, a bad result in midwifery is too frequently the result of bad judgement. Moreover, the only way to obtain a real knowledge of the bad results of midwifery, and among other things of the abuse of the forceps, is to attend the practice of the gynaecological ward and yet this is not compulsory. More recently in some hospitals, it is true, the deans have refused to "sign up" students unless, and until, they have been in-patient gynaecological dressers; but the General Medical Council did not insist on the students holding these posts, and the more cautious deans refused to adopt such an attitude. Most of the students, being aware of the fact that they only had to serve three months either in the in-patient or out-patient department, chose the latter because it gave them less trouble.

The bad results of midwifery are partly due to want

towels—in most cases not. The doctor may very likely reply: This cannot be helped—the patient cannot afford such luxuries; but I am not dealing with the doctor's responsibilities, but with the abuse of the forceps extraction as an operation.

The position of a nation depends upon the number and efficiency of its population. In the absence of sufficient hospital accommodation for lying-in women the local authority should be responsible for supplying the proper aids to childbirth. In comparison with other operations the forceps extraction is at a further disadvantage, for whereas the surgeon in practically all cases is able to carry out the best treatment for the patient, the obstetrician may have no such choice, and he may not have had any opportunity of treating the patient until one procedure only is available, and that not the best.

With the ordinary operation the surgeon is not influenced by the patient or her relatives trying to persuade him to operate; on the contrary the strongest objections may be raised by one or the other. How different is the lot at times of the doctor attending a confinement—constantly being reminded that Mrs. So-and-so had instruments and the labour was terminated easily and quickly.

#### MECHANISM OF LABOUR.

The abuse of the forceps operation may be regarded from quite a different point of view from that which I have dealt with up to now. Normal labour consists of certain regular stages, and is a natural process, just as much as defaecation and micturition. At times complications may intervene in any of these physiological acts, so that they may become pathological; but it is in the case of labour only that such transmutation from the physiological to the pathological can be ascribed to the interference of the medical attendant. The mechanism of labour is arranged to get the best possible result in the shortest length of time. The child is not propelled downwards until the cervix is fully dilated, which dilatation Nature accomplishes gently, slowly, and evenly, the contractions of the upper segment pulling the cervix over the head. Then as the head is advancing through the pelvis from the brim to the outlet its smallest longitudinal diameter, by the movements of flexion, internal rotation, and extension, is accommodated to the largest diameter of the pelvis, so that the pressure on maternal and foetal tissues is reduced to a minimum, and being moulded very slowly. In addition, as the foetus passes through the vagina the levatores ani are stretched and relieved from strain according to whether there is a "pain" or not.

The operation of the forceps extraction must always interfere with the normal mechanism, and in many cases very disastrously. If the forceps is applied before the cervix is fully dilated the dilatation is now more forcible, and also uneven, while instead of the head being pulled up by Nature it is pulled down by the forceps, the total result being some injury to the mother, often serious injury. Labour is more quickly terminated by the use of the forceps, otherwise the doctor would be using this instrument. This means that with the forceps extraction insufficient time is allowed for the proper flexion of the head, and an unmoulded head is much more difficult to deliver because the diameter engaged is larger than it should be. Again, unless the greatest care is taken during extraction to pull only when a uterine contraction occurs, the levatores ani will be unduly stretched—they will not be given that period of rest which Nature demands. Lastly, the movements of flexion, internal rotation, and extension are interfered with, and when axis-traction forceps are not used, the result by the ordinary forceps notably causing premature extension of the head.

My experience as an examiner of most of the examining bodies in England has taught me that less attention is paid by students to the mechanism of labour than to any other subject in midwifery. I cannot help thinking that the lack of interest in this subject remains with many of them for life, otherwise many emergencies, necessitating, as the practitioners think, the application of forceps, would, like the old soldier, "slowly fade away."

That forceps are often used unskillfully is due to the

fact that, in the past at any rate, a large number of men have not seen them employed before going into practice. The method of using the forceps is open to abuse. The instrument can be used as a tractor, compressor, rotator, lever, and stimulator. In my opinion the only warrantable use to which the forceps should be put is that of stimulating uterine contraction. I presume none except the most ignorant would in these enlightened days think of using the forceps as a lever. All the cases which I have known in which such a use had been made of the instrument ended disastrously for the mother, either in fearful laceration or in her death. I know that many practitioners think that in cases of persistent occipito-posterior positions rotation with the forceps is a good method of treatment, and that it is often used as a first choice. In nearly every case, especially when the patient has been watched carefully in the early stages of labour, it is possible to rotate the head and shoulders with the hands. The child certainly is more likely to be injured by rotation with the forceps, and I have seen most serious laceration following such attempts on the mother. To use the forceps to make the diameter of the head smaller—that is, as a compressor—is absolutely wrong. This instrument must exert a certain amount of compression unfortunately, but this must be avoided as far as possible by allowing its handles to remain loose at frequent intervals. There remains traction, the one proper use to which this instrument can be put. Even this use, however, is frequently abused. The force used should be strictly limited. If great force has to be used—and not infrequently one meets doctors who state that they had to pull with all their strength, and perhaps with the aid of one foot against the bed—this is a sure indication that forceps extraction was not the correct treatment.

It is an abuse of the forceps to use it too soon or too late. The forceps should never be applied too soon—that is, before the cervix is fully dilated, either by Nature or, in cases of necessity, by hand, or, in cases of disproportion, before the head has had time to mould. To apply the instrument in exhaustion of the uterus, or after the death of the child, is to apply it too late.

It is wrong to deliver the child quickly unless such is absolutely indicated. A slow delivery is not nearly so likely to injure the mother or the child. It is not fair on the forceps to use it before emptying the bladder with a catheter, neither is it fair on the patient. A vesico-vaginal fistula may easily result in the absence of such precaution, and yet I have heard some of my friends say that they are so apt to forget this that they always keep a catheter tied to one blade of the forceps. Lastly, if difficulty is experienced in applying the forceps by one who is accustomed to use this instrument, this is generally an indication that the case is not one really suitable for forceps but would have been better treated by some other procedure.

Baudelocque remarked that the obstetric forceps was the most useful instrument that had ever been invented. I have been criticized for suggesting that this further supplication should be added to the Litany: "From the obstetric forceps, good Lord, deliver us." So frequently, however, is this instrument used that one might be justified in thinking that for generations there had been a supplication: "With the obstetric forceps, good Lord, deliver us."

The use of the forceps may be necessary in the interests of the mother or the child, but I take it that such action can only be justified if, in the first case, the mother is not worse off than before the forceps was used, and, in the second, if the child is born uninjured.

Advocates of the frequent use of the forceps maintain that the operation shortens the woman's suffering and that it diminishes her risk, and also that of her child. It is true that the suffering due to labour pain is shortened, but is this worth the increased risk, nay, the certainty in some cases, of lifelong suffering from injury or infection, when it can be mitigated by far less dangerous remedies? Then many assert that they get no tears, or less severe tears, when using the forceps. I doubt it. They may not recognize the lacerations of the cervix, or of the vaginal walls, and at any rate it is quite certain that the

## British Medical Journal.

SATURDAY, OCTOBER 6TH, 1923.

## THE CENTENARY OF THE "LANCET."

Our contemporary the *Lancet* has celebrated its hundredth birthday by issuing a supplement which, while it describes the rise and progress of the paper, is also a very valuable contribution to the history of medical journalism in this country. For although long before its first appearance there were monthly and quarterly medical periodicals, yet however weighty their scientific contributions might have been they were of small influence, and after that time the weekly journals quickly became the only ones that counted in the world of medical politics. The *Lancet* to-day, unlike human centenarians, shows no sign of senile decay, but is still full of vigour.

When what was then a humble little octavo first appeared it is not probable that anyone—even its editor—foresees that it would soon become a power in the land, and incidentally that it would prove to be a very valuable property for its originator.

A weekly medical journal was a startling innovation; its unrestricted criticism of important personages and of existing medical institutions, and its advocacy of reform couched in strong language attracted wide notice. It was read by medical reformers and by medical reactionaries as well as by many of the general public.

Indeed, that his journal should serve as a liaison between the profession and the lay public was one of the avowed objects of the founder. It would be idle to deny that in its youthful days it was often scurrilous and sometimes unfair in its criticisms and comments, and some specimens of *Wakley's* bludgeonings are given at page 616. We can, however, recognize that *Wakley's* prime motives were good, though his methods were often reprehensible.
